Mr. Thomas Jones says he knew nothing about any request from St. Mary's that the case might be returned, although he admits that he knew the boy went into St. Mary's to be operated upon, and that only the accident of catching scarlet fever accounted for his being in the Pendlebury Hospital at all, and Mr. Jones contends that he was quite justified in operating upon the case.

Such conduct as this on the part of a hospital staff, which I can only designate as ungenerous, discourteous, and fatal to all inter-hospital good feeling, ought, I think, to be brought before the notice of the profession.

I remain, Sir, yours faithfully,

J. H. EWART,

Manchester, Sept. 8th, 1880.

Surgeon to St. Mary's Hospital.

WESTMINSTER HOSPITAL: A CORRECTION.

To the Editor of THE LANCET.

SIR,—In your last impression you refer to a "Westminster Hospital School of Anatomy, Physiology, and Operative Surgery." Allow me to state that the only school connected with the Westminster Hospital is the Westminster Hospital Medical School.—I am, Sir, your obedient servant,

A. PEARCE GOULD,

Sub-Dean of Westminster Hospital Medical School.

Sept. 13th, 1880.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons, on the 3rd inst., Mr. O'Connor Power gave notice of a question for Monday, referring to an article in a medical journal on the administration of the law relating to public health in Ireland, and inquiring what measures the Government propose to take for enforcing the Public Health (Ireland) Act; but on Monday the House did not sit, and on Tuesday the question was not upon the paper.

On the 4th inst., petitions for redress of grievances were received from the following officers of the East Indian army medical department:—Surgeon-Major William Henry Kirtton, Surgeon-Major Thomas Miller, Surgeon-Major George Alder Watson, Surgeon-Major Alfred Eteson, and Surgeon-Major James Howard Thornton.

On the 8th inst., just previous to the prorogation, Sir H. D. Wolff asked the Marquis of Hartington what decision had been come to with regard to the chargeability upon the rates of London, Portsmouth, and other towns of military and other lunatics brought home from India. Lord Hartington replied that the correspondence with the Indian Government on the subject was concluded. The decision of the India Office was that the matter was one which rather affected the War Office. However, he should be glad if the hon. member would see the correspondence, and before next Session he would consider whether it could be laid upon the table of the House.

Obituary.

WILLIAM O'CONNOR, M.D. &c.

WE have to record the death of Dr. William O'Connor, senior physician to the Royal Free Hospital, which took place on the 3rd inst., at his residence in Upper Montagu-street, Montagu-square, W. He had been in practice in this metropolis for close upon forty years, during twenty-five years of which he was an active member of the staff of the institution above mentioned. He was known principally for his treatment of stomach and neuralgic affections, and for his success in the management of the diseases of children.

Dr. O'Connor was descended from an ancient Kerry family, remarkable for the great number of members whom it has afforded to our profession, including several of his brothers, one of whom, Dr. Maurice J. O'Connor, is still in practice in London. The deceased was a direct lineal descendant of the celebrated Bernard O'Connor, M.D., who died in 1698, and who is historically noted for his treatise "Evangelium Medici," and his accurate diagnosis in the case of the Duchess of Bedzevil, sister of the King of Poland, to whom he was physician.

Of the three surviving sons of the deceased, one, Arthur O'Connor, is M.P. for Queen's County; another occupies an official position; and the third, Bernard O'Connor, M.D., M.R.C.P. Lond., physician to the Westminster General Dispensary in Gerrard-street, Soho, is in consulting practice in Brook-street, Grosvenor-square. It is a curious fact that the only possessors of the name "O'Connor" who have figured on the roll of the Royal College of Physicians during the last three hundred years should bear the same Christian name—the one the last-named son, and the other the physician to the Polish king already referred to.

EDWARD AMPHLETT, M.A., M.B., CANTAB.,
F.R.C.S. ENG.

THE death of Mr. Amphlett, Assistant Surgeon and Pathologist to Charing-cross Hospital, Assistant Surgeon to the Central London Ophthalmic Hospital, and Clinical Assistant at Moorfields, occurred on September 9th, at his residence in Weymouth-street. Mr. Amphlett sprang on his father's side from an old Worcestershire family and was the son of a well-known member of the profession practising in Birmingham, and a nephew of Sir Richard Amphlett, of Wychbold Hall, near Droitwich, late Lord Justice of Appeal; whilst on his mother's side he was nearly related to the late Dr. Male, a name of note in the history of

Medical Jurisprudence. Born in the year 1848, and educated for the sea, he served as a midshipman in the Royal Navy for several years till invalidated out on account of asthma, which was the cause of so much suffering to him throughout his life. Whilst in her Majesty's service Mr. Amphlett saw a great deal of different parts of the world, and throughout his life retained a strong attachment for nautical matters, in which he took a keen scientific interest, as shown by his adhesion as surgeon to the ranks of the Naval Artillery Volunteers, with whom he recently went a cruise on board H.M.S. *Esk*. Nothing indeed ever afforded him greater delight than meeting with an old sea comrade and messmate.

On leaving the Navy he determined to enter the medical profession, and having graduated at Cambridge through the mathematical tripos, he came up to Guy's Hospital, where he held all the posts open to a student, and having taken his Bachelor of Medicine degree at Cambridge and the Fellowship at the College of Surgeons in a brilliant manner, was finally appointed assistant surgeon to Charing-cross Hospital. From this time Mr. Amphlett devoted himself with much assiduity to the practice of his profession, and particularly to eye diseases, for the special study of which he attended the Vienna School for some months; he lectured also to the St. John Ambulance classes, and recently to those of the University Extension Scheme.

His promising career was cut short in a most untoward manner on Thursday morning, Sept. 9th. The deceased had been suffering with unusual severity from asthma, which was aggravated by exceptionally heavy out-patient work and severe mental distress, and after a broken night's rest he was found by his servant to be extremely ill. His neighbour, Dr. Murrell, was instantly with him, followed shortly by Dr. Colcott Fox, and later by some of his colleagues. Mr. Amphlett was found to be under the influence of a large dose of morphia and chloral, and rapidly passed into a state of profound stupor, with contracted pupils and great lividity and coldness of the surface. Every possible remedy was tried, such as emetics, without effect; forcible roussings and cold douchings, with subsequent stimulation of the body surface with brandy, towels, and hot-water bottles, strong enemata of coffee, the interrupted current, and nitrite of amyl. Artificial respiration carried out for about an hour raised for a time false hopes, and the injection of sulphate of atropia (one fortieth of a grain), followed by a second after carefully watching the effect of the first, caused the gradual dilatation of the pupils; but all efforts proved useless, and he died in about two hours. Dr. Murrell found post mortem that the body was generally healthy, excepting that the lungs were markedly emphysematous and loaded with serous fluid, and the right side of the heart dilated.

By Mr. Amphlett's death the profession loses a young member of more than ordinary promise; for, inheriting ability from both sides of his family, he was known amongst his professional brethren and an unusually wide circle of acquaintance to be possessed of considerable intellectual vigour. Harassed by ill health and impatient of delay in his profession, he was often seen under disadvantageous circumstances; but those intimately acquainted with him knew Edward Amphlett to be a warm-hearted and steadfast friend, a man of the strictest honour, and when not depressed by illness a most agreeable and entertaining companion, replete with information on a great variety of subjects, and the possessor of abilities of a high order. Mr. Amphlett was a distinguished Freemason, and the Past-Master of several important lodges.

DEPUTY INSPECTOR-GENERAL JOHN STIRLING,
M.D., M.R.C.P., L.R.C.S. EDIN.

WE much regret to record the death of Deputy-Inspector-General John Stirling. He was born in London in the year 1816. His father before him was a surgeon in the Royal Navy, but he retired early and practised many years in Halifax, Nova Scotia. Dr. John Stirling when a student was distinguished for diligence and devotion to his profession. He was educated at the Royal Infirmary, Edinburgh, and afterwards held for some time the post of house-surgeon. He was then appointed resident medical officer to the Lying-in Hospital, where he studied midwifery and diseases of women, under the late Sir James Simpson. In 1840 he entered the Royal Navy as assistant surgeon, and went out with the Niger Expedition, and in consequence

of his experience in this quarter of the globe he was again sent out in 1845 to the coast of Africa on exploring service. He afterwards served on the Mediterranean Station, and was present at the blockade of the Piræus. In 1850 he was sent to the south-east coast of America, and in 1852 was appointed surgeon to H.M.S. *Fury*. The cholera was then raging at Balpk, and the disease attacked a large fleet of transports. In the emergency Dr. Stirling volunteered his services, and by his devotion and courage won the admiration of both officers and men. During the siege of Sebastopol he served on board the *Queen*. He was subsequently staff surgeon to the Naval Hospital at the Cape of Good Hope, and his last appointment was to the Plymouth Hospital. In 1870 he was raised to the rank of Deputy-Inspector-General of Hospitals and Fleets.

Dr. Stirling was an able surgeon, and his kind and generous nature gained the esteem of all who knew him. He died at Southsea on August 30th, 1880.

J. C. HIRSCHFELD, M.B., A.M., OF BANFF.

THE death of this gentleman, on the 7th inst., took place under peculiarly melancholy circumstances. On the day mentioned Dr. Hirschfeld, accompanied, amongst others, by his little son and a skilled seaman, embarked in his pleasure-boat for a sail along the coast. A pleasant run was made to Portsoy, where the party landed and stayed a few minutes. Soon after putting off again, a squall struck the boat; she capsized and sank, and the doctor, his son, and the seaman were drowned. The following sketch of the deceased's career is from the *Banff Journal* :—

"Dr. Hirschfeld was only thirty-three years of age. A man of remarkable strength and activity, he was an expert swimmer, and, unencumbered, might have kept himself afloat for a long time, or even swam to the shore. Born at Trieste, he was the only son of Mr. Philip Charles Hirschfeld, now of the Isle of Man, and who has become familiar in Banffshire society in recent years through his periodical visits to members of his family resident in the county. Dr. Hirschfeld was educated at Edinburgh High School and University. He graduated M.B., C.M., in 1869, and was also a licentiate of the Royal College of Surgeons. During the course of his medical studies he acted for some time, first as house-surgeon, and afterwards as physician to the Royal Infirmary, Edinburgh. On taking his degree he proceeded to Germany, and as a member of the British Surgical Ambulance took a part in the Franco-Prussian War during 1870-71. He was in service before Metz, and at the investment of Paris, and always volunteered to go to the front. While with the Prussian Army he performed some notable surgical operations. Returning home he found his first professional employment at Banff in the end of 1871, when he was assumed as a partner by Dr. Manson. During the nine years of his residence in Banff, Dr. Hirschfeld gained many friends, and was universally respected. He married, six years ago, Jane Elizabeth, daughter of the late William Chalmers, manager of the Northern Insurance Company, at Aberdeen. They had but one child, the bright boy of three years who was lost along with his father."

A correspondent writes of the late Dr. Hirschfeld :—"He was an ornament to his profession. I knew him intimately, and can say that he was one of the best of men. His skill as an operator was great. His heart was in his work, and he was likely to come to the front rank in the growing combat with disease."

JAMES SIMPSON, M.D. ABERD.

DR. SIMPSON was born in Aberdeen, and educated at Mr. Rattray's, the Grammar School, and King's and Marischal Colleges. He became Demonstrator of Anatomy in the University of Aberdeen, and soon afterwards was elected house-physician to the Royal Infirmary. At the end of his curriculum he graduated M.D. with highest honours, receiving the Murray Gold Medal as the most distinguished student of his year. He was at once appointed Assistant Professor of Anatomy, an office which he held for a year. He then settled in practice in his native town, and conducted private classes for the instruction of medical students. Being desirous of more active life, Dr. Simpson turned his thoughts to the Indian Medical Service, in his examination for which he obtained the highest number of marks amongst fifty-two competitors. It was whilst preparing for this exa-

mination that he was seized with the illness from which he never thoroughly recovered. This was regarded by Sir Joseph Fayrer and Professor Maclean as an acute attack of malarial fever, contracted by exposure all night in an open boat, stranded on a mud-bank in Southampton water. When slightly recovered, he obtained two months' sick leave, though he was under special orders by telegraph to leave for India. Returning to Aberdeen, he was married on the 24th ult. to a daughter of Mr. Smith of Nigg. At Glasgow, on his way south, after his marriage, feeling still unwell, he consulted Dr. Gemmell, in the absence of Professor Gairdner. Before he could comply with the advice given him to return home at once symptoms of embolism of the femoral artery came on. He was, however, able to reach Aberdeen, where he expired on the 10th inst., at the early age of twenty-seven years.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Sept. 2nd:—

Harral, Charles Henry, Kirkgate, Leeds.
Head, Philip Alexander Dewar, Clapton.
Hepburn, William Alexander, Coxhoe, Durham.
Morgan, William Pierce, Dowlais, Glamorganshire.
Smith, John, Commercial-road, E.
Watson, Archibald, Paris.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Ernest Hudson, University College; John Joseph Faraker, Guy's Hospital; Richard Hamilton Cowan, London Hospital.

Passed their examination and received certificates to practise on Sept. 9th:—

Braganza, Bellarmin Moscardi, Bombay.
Ford, Lewis Frederic, Highgate.
Northcott, Arthur, Albert-street, N.W.
Rodway, Edwin Augustus, Taunton, Somerset.

Passed the Primary Professional Examination on the same day:—

Ashley Bird and Thos. Ruell Atkinson, St. Bartholomew's Hospital;
John Henry Robinson, St. Mary's Hospital; Thos. Ricketts Moore, Charing-cross Hospital; Chas. Henry Duff, Herbert Edward Deane, and Edward Davis, Middlesex Hospital; James Prytherch James, St. Thomas's Hospital; George Toussaint Girdler, Westminster Hospital.

THE death, by suicide, is announced of Mr. Robert Hughes, M.R.C.S. Eng., of Woodbridge, Suffolk.

A GRAND BAZAAR, in aid of the funds of the Sick Children's Hospital, Brighton, is to be held in the Dome and the Corn Exchange.

MR. JOSHUA JOSEPH BIRD POPJOY, L.R.C.P. Lond., M.R.C.S. Eng., has been placed on the Commission of the Peace for Accrington.

THE salary of Mr. P. Cowen, M.R.C.S. Eng., medical officer for the Upper Holloway West District of the Islington Union, has been increased from £60 to £80 per annum.

THE LIBRARY of the Royal College of Surgeons, which has been closed for cleansing, will be re-opened on Friday, the 1st of October, and the Museum on the following Monday.

MR. W. H. HAYDEN, M.R.C.S. Eng., who, for the third time, fills the office of Mayor of High Wycombe, Bucks, has been placed on the Commission of the Peace for the borough.

SIR JAMES PAGET, Bart., will take the chair at the annual dinner of the Old Students of St. Bartholomew's Hospital, on Friday, October 1st, in the Grand Hall of the Hospital.

THE Registrar of Killishannig, Mallow (says the *Western Morning News*) reports the death of Cornelius M'C—, at 111 years of age, and says the age is well authenticated, it being well known in the family that he was born in the year in which his father took a lease of a farm, and that was in 1769.

POISONING BY SULPHURIC ACID.—Last week, at Newtownards, a boy aged four years got access to some sulphuric acid, and swallowed about a quarter of a wine-glassful. Medical aid was obtained, but all treatment was unavailing, and the child died the same day.

Dr. FAUSSETT, having resigned from ill-health the appointment of medical officer of the Clontarf and Howth Dispensary District, the dispensary committee have recommended that he should receive the full retiring allowance to which he is entitled after forty-three years' service. The committee have also expressed their regret at the cause assigned for his resignation, and their appreciation of the value of his services during the long period that he has held the position.

PRESENTATION.—Last week Mr. J. B. Brereton, L.K.Q.C.P.I., was presented with a library clock, and a valuable case of instruments, by the members of the "Church of England Mutual Improvement Society," in "grateful acknowledgment, not only of his professional services, but also of the assistance rendered by him in the institution of the Evening Classes of the Society, and in the promotion of other efforts for the intellectual, moral, and spiritual benefit of the parishioners generally."

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

ANNINSON, J., M.D., M.R.C.S.E., has been appointed an Honorary Medical Officer to the Preston and County of Lancaster Royal Infirmary, vice W. B. Anninson, M.D., resigned.

ANNINSON, W. B., M.D., M.R.C.S.E., has been appointed Consulting Honorary Medical Officer to the Preston and County of Lancaster Royal Infirmary.

ARCHER, R. S., A.B., M.B., M.Ch., has been appointed Honorary Visiting Physician to the Netherfield Institution for Infectious Diseases, Liverpool.

BALLANCE, C. A., L.R.C.P., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to St. Thomas's Hospital.

BRIIGGS, H., M.B., M.R.C.S.E., has been appointed Senior House-Surgeon to the Stanley Hospital, Liverpool.

BUTLER, H. P., M.R.C.S.E., L.R.C.P., has been appointed House-Physician to St. Thomas's Hospital.

COX, W. A., M.R.C.S.E., L.S.A.L., L.M., has been appointed Medical Officer to the Kensington and Chelsea District Schools at Banstead, Surrey.

DAVIES, J., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Tregynon District of the Newtown and Llandiloos Union.

DUNBAR, A., M.B., C.M., has been appointed Honorary Visiting Physician to the Netherfield Institution for Infectious Diseases, Liverpool.

ETHERIDGE, C., M.R.C.S.E. &c., has been appointed Admiralty Surgeon and Agent, vice Williams, retired.

FIRTH, E. H., M.R.C.S.E., L.R.C.P., has been appointed House-Surgeon to the Blackburn and East Lancashire Infirmary, vice Wilkins, resigned.

GREVES, E. H., M.B., has been appointed Demonstrator of Anatomy in the Liverpool Royal Infirmary School of Medicine, vice H. Briggs, M.B., resigned.

HAINES, A. H., M.R.C.S.E., L.S.A.L., has been reappointed, for one year, Medical Officer of Health for the Port of Wisbeach.

HAMMOND, T., L.R.C.P.L., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Halifax Infirmary, vice R. Scott, M.D., C.M., resigned.

HATTON, G. S., M.B., M.S., M.R.C.S.E., L.S.A.L., has been appointed House-Physician to St. Thomas's Hospital.

HAYWARD, J. W., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Whitstable District of the Blean Union.

KER, Miss A. J. S., M.D., L.M., L.K.Q.C.P.I., has been elected Assistant Resident Medical Officer to the Children's Hospital, Birmingham, vice L. A. Middleton, resigned.

LAWFORD, J. B., M.D., M.R.C.S.E., L.R.C.P., has been appointed Assistant House-Physician to St. Thomas's Hospital.

LUNN, J. R., L.R.C.P., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to St. Thomas's Hospital.

LYNCH, F. E., L.R.C.S.I., L.K.Q.C.P.I., has been appointed Assistant Medical Officer to the Lambeth Infirmary, vice G. A. Hamerton, M.D., resigned.

MACDONALD, K. H., M.D., has been appointed Surgeon to the Prison, Cupar, Fife.

MACPHERSON, A., M.B., has been appointed Junior House-Surgeon to the Stanley Hospital, Liverpool.

MICKLEY, A. G., M.B., L.R.C.P.L., M.R.C.S.E., has been appointed Resident Medical Officer at the Workhouse of the Islington Union.

MURRAY, W., M.B., C.M., has been appointed Medical Officer to Parkfield Collieries, near Bristol, and District Surgeon to Midland Railway Friendly Society, vice C. M. Heim, resigned.

NEVSHOLME, A., M.R.C.S.E., L.S.A.L., has been appointed Resident Accoucher to St. Thomas's Hospital.

PARETTE, J., L.R.C.P. Ed., L.S.A.L., L.M., L.R.C.S. Ed., F.C., has been appointed Junior Medical Officer to the Exeter Friendly Societies' Medical Association.

PARKER, W. R., B.A., M.B., M.R.C.S.E., has been appointed Resident Medical Officer to the Netherfield Institution for Infectious Diseases, Liverpool.

REID, J., M.D., M.B., C.M., has been appointed Medical Officer to the Fifth District of the Fulham Union, vice M. A. Gleeson, resigned.

RICHARDSON, C. B., M.R.C.S.E., L.R.C.P., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

ROBINSON, J., M.D., has been appointed Certifying Surgeon for the Turton District, near Bolton. Also Medical Officer for the Turton District of the Bolton Union. Also Medical Officer of Health for the Urban Sanitary District of Turton. In respect of all the offices mentioned, vice J. Robinson, M.R.C.S.E., deceased.
WALKER, H., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the Third District of the Fulham Union, vice B. E. Sparell, resigned.
WALTERS, F. R., M.R.C.S.E., L.S.A.L., has been appointed Assistant House-Physician to St. Thomas's Hospital.
WEIGHT, R. H., M.D., M.B., C.M., has been appointed Senior House-Surgeon to the Preston and County of Lancaster Royal Infirmary, vice Dr. Langdon, resigned.

Births, Marriages, and Deaths.

BIRTHS.

BERNAYS.—On the 5th inst., at Old Charlton, S.E., the wife of Herbert L. Bernays, M.R.C.S.E. &c., of a son.
FINLAY.—On the 2nd inst., at Montagu-street, Portman-square, the wife of David W. Finlay, M.D., of a daughter.
LEE.—On the 13th inst., at Maddox-street, the wife of Robert J. Lee, M.D., of a daughter.
RAWLINS.—On the 6th inst., at Gordon House, Highgate-road, the wife of William Peter Rawlins, M.D., of a son.
TURNER.—On the 8th inst., at Northumberland House, Green-lanes, N., the wife of T. B. Turner, M.R.C.S.E., of a daughter.
TYLECOTE.—On the 5th inst., at Sandon, Staffordshire, the wife of J. H. Tylecote, M.D., of a son, still-born.

MARRIAGES.

CHITTENDEN—FAWKNER.—On the 15th inst., at St. George's, Hanover-square, W., Charles Chittenden, M.D., late of Her Majesty's Royal Navy, youngest son of John Frank Chittenden, M.D., and grandson of the late John Frank Chittenden, M.D., to Evelyn, eldest daughter of Thomas Fawcner, Esq., of Cornworthy Lee, late of Manchester.
BATT—WAKE.—On the 14th inst., at the Parish Church, Ecclesfield, by the Rev. E. H. Bucknall Estcourt, M.A., Rector of Eckington, assisted by the Rev. Alfred Gatty, D.D., Sub-Dean of York and Vicar of Ecclesfield, and the Rev. Nathan Jackson, M.A., Vicar of Easingwold (brother-in-law of the bridegroom), Charles Dorrington Batt, M.B. Lond., fourth son of the late Edward Augustine Batt, Surgeon, of Witney, Oxon., to Isabel, eldest daughter of Bernard Wake, Esq., of Abbeyfield, Sheffield.
DENNISTON—GUTHRIE.—On the 9th inst., at Withington Presbyterian Church, Manchester, by the Rev. Charles Moinet, M.A., James Denniston, M.D., of Dumoon, Argyllshire, N.B., to Agnes, daughter of Alexander Guthrie, Esq., of Broadoak, Withington, Manchester.
GREENWOOD—STEVENS.—On the 14th inst., at St. John's Church, Chatham, by the Rev. G. W. A. Lawrance, Arthur Greenwood, L.R.C.P.L., M.R.C.S.E., of 178, Cold Harbour-lane, S.E., to Ann Ellen (Annie) Stevens, second daughter of George Stevens, Esq., of 8, Ordnance-terrace, Chatham. No cards.
JOHNSTON—MOORE.—On the 31st ult., at the Abbey Church, Tewkesbury, by the Vicar, the Rev. Hemming Robeson, assisted by the Rev. Thurston Rivington, E. Cocks Johnston, M.R.C.S.E., of Bristol-street, Birmingham, to Edith Mary Moore, eldest daughter of B. T. Moore, J.P., of Tewkesbury.
REID—MUNNS.—On the 2nd inst., at St. Martin's Church, Canterbury, by the Very Rev. the Dean of Canterbury, assisted by the Rev. William Newman and the Rev. T. H. Maitland, Thomas Whitehead Reid, M.R.C.P. Ed., M.R.C.S.E., L.R.C.P.L., to Emily Eliza, third daughter of Colonel Munns, of St. Martin's Priory, Canterbury.

DEATHS.

AMPHLETT.—On the 9th inst., at Weymouth-street, Portland-place, Edward Amphlett, F.R.C.S., younger son of the late S. Holmden Amphlett, in his 32nd year.
BAKER.—On the 9th inst., at his residence, 6, Gambier-terrace, Hope-street, Liverpool, John Copleston Baker, M.D., aged 43.
CAMPBELL.—On the 9th inst., William Campbell, M.D., F.R.C.S.E., of 13, Westbourne-place, Eaton-square, London (drowned at Redcar while saving a boy).
FORBES.—On the 30th ult., at North Silver-street, Aberdeen, Alexander Forbes, M.D., aged 38.
HEWETT.—On the 29th ult., at his residence, The Lodge, Palmer's-green, Southgate, John Dickason Hewett, M.D., only son of the late George Goodman John Hewett, Surgeon, Royal Navy, of Hilton, Hunts, aged 64.
IMRAY.—On the 22nd ult., at Dominica, West Indies, Dr. John Imray, in his 70th year.
MOORE.—On the 4th inst., at 2, Osborne-terrace, South Circular-road, Dublin, Malcolm Henry Moore, M.B., aged 23.
O'CONNOR.—On the 3rd inst., suddenly, at 30, Upper Montagu-street, Montagu-square, William O'Connor, M.D., Senior Physician, Royal Free Hospital, aged 63. R.I.P.
SEYMOUR.—On the 8th inst., Dr. William F. Seymour, Medical Officer of Balinglass Union Workhouse, aged 39.
SIMPSON.—On the 13th ult., at Sibi, South Afghanistan, John Simpson, Surgeon, Bombay Army, aged 33.
SUCHE.—On the 5th inst., at Westin-super-Mare, George Suche, M.D., F.L.S., F.R.G.S., &c., aged 82.
WATSON.—On the 3rd inst., at Oakfield, Reigate, Mary Watson, sister of Sir Thomas Watson, Bart., M.D., in her 86th year.
WILLIAMSON.—On the 3rd ult., at Grahamstown, Cape of Good Hope, John Edwin Williamson, M.D., formerly of Nantwich, Cheshire, aged 45.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

AN UNCOURTEOUS LOCUM TENENS.

A CORRESPONDENT sends us a very bad account of his experience of a locum tenens, who, by his discourtesy, swearing, &c., drove patients away, was dissatisfied with four meat meals a day, &c. We can only by giving publicity to such an experience put practitioners on their guard. There cannot be many such gentlemen about. Principals, in engaging a locum tenens, should inquire not only as to their qualifications, but their manners.

Mr. James Worthington.—Galton on the Construction of Hospitals (Macmillan and Co.); Hospital Plans: Five Essays relating to the Construction, Organisation, and Management of Hospitals, contributed for the Use of the Johns Hopkins Hospital of Baltimore (Sampson Low, Marston, and Co.)

L. E. P. can only recover as a surgeon, and for surgical treatment.

THE STATISTICS OF ANTI-VACCINATIONISTS.

To the Editor of THE LANCET.

SIR,—Having occasion to look through some of the back numbers of THE LANCET, my attention was drawn to the figures quoted in one of your leaders for July 17th, 1880, from a letter written to a northern paper by Mr. J. T. Hibbert, M.P., the Parliamentary Secretary of the Local Government Board. I thought these figures looked very extraordinary, and, stimulated by your hint as to the accuracy of the text, I took the trouble of getting at the statistics as given by the Registrar-General (Abstracts for 1874-75). I found the statistics quoted by Mr. Hibbert totally wrong, and it surpasses my comprehension how the figures referred to were obtained. The following were the figures quoted:—"Increase of mortality amongst infants in 1875, 26,000 (all causes); increase from diarrhoea amongst infants from 5143 in 1874 to 15,477 in 1875; increase from bronchitis from 2506 in 1874 to 14,506 in 1875; increase from syphilis from 255 in 1874 to 1554 in 1875; decrease from small-pox from 1074 in 1874 to 142 in 1875."

The real statistics are as follows:—Increase of mortality amongst infants in 1875, 6756; increase from diarrhoea among infants from 13,988 in 1874 to 15,522 in 1875; increase from bronchitis from 12,580 in 1874 to 14,500 in 1875; increase from syphilis from 1484 in 1874 to 1554 in 1875; decrease from small-pox from 306 in 1874 to 90 in 1875.

It seems to me that had Mr. Hibbert taken the trouble to test the accuracy of the statistics presented to him by anti-vaccinators, he would not have given his support to the illogical and hazardous Amendment of the Vaccination Act, which was at one time under Government patronage. If the statistics of the opponents of vaccination are cooked in this fashion, Mr. Hopwood and his supporters may cease from troubling the Government for returns from the Registrar-General, since a useful and convincing table of such facts might be evolved from the inventive brain of one of the vaccination "martyrs," upon whom "multiple" fines have wrought their maddening effects.

I am, Sir, yours &c.,

Putney, Sept. 11th, 1880.

A. WALKER, M.D.

P.S.—I deny that any increase has taken place in the deaths of infants from syphilis since 1870, save what may fairly be ascribed to increase of population.

THE CHINESE AS PATIENTS.

MR. ANDERSON, L.R.C.P., stationed in Formosa as agent of the English Presbyterian Church in connexion with the Edinburgh Medical Missionary Society, writes:—

"The Chinese make, on the whole, very good patients. Occasionally some of them try our patience not a little. One gets a four days' supply of medicine away with him, the recipe bearing on it, 'a spoonful three times daily after each meal.' He comes back next morning for more, thinking to flatter you by stating that he drank the former quantity at one dose! Another has his arm carefully put up in splints, and on his next visit he brings his dressings in a separate parcel. They are great believers in internal administration, and, although he have only a cut finger, it is difficult for a Chinaman to see why he should not get some medicine to 'eat.' They have peculiar palates, many of them, and can drink castor oil *ad nauseam*—a stage which is not so easily reached in their case as it is in ours. Here, as elsewhere, the medical has all along been found to be a valuable auxiliary to the general mission work."

Verbena will get the information he wants by applying to the Charity Organisation Society; or the Secretary of one of the good provident dispensaries for copy of Rules, Report, &c., say Northampton.

INSALUBRITY OF WEST-END DISTRICTS.

To the Editor of THE LANCET.

SIR,—I live in a highly respectable West-end suburb. Immediately adjoining the rear of the house in which I reside is a large open space, which, however, is entirely surrounded by houses. A portion of this space (close to my residence, and in an angle between the street in which it is situated and another street) is occupied by a number of small vegetable gardens, access to which is gained by an as yet unformed road. All along this road for a considerable distance (in the angle between two streets referred to already) are heaps of stable manure and other refuse, brought from I cannot tell where, to be used in fertilising the gardens alluded to. These heaps are there all the year round, being constantly replenished. All through the recent summer they have been there, soaked with rain one day, and sweltering in the sun the next. There is also immediately adjoining the unformed road mentioned a large green pool of stagnant water, which receives all the surface drainage of the extensive patch of vegetable gardens, and is, of course, highly charged with decomposing vegetable matter. During the late very hot weather, when we had some very heavy dews at night, the stench of decomposing vegetable matter—the well-known "cabbage-water" smell—was so strong that I have been more than once awoken from sleep by it, having, as is my usual custom, had my bedroom window open, and this window not immediately overlooking the cabbage-garden, but facing the street. I wrote twice to the sanitary department of the parish in which I live, and after some delay received a note from the health officer, stating that he "had inspected the ground and its surroundings," but "did not see anything to call for the interference of this department, there being nothing which, in my opinion, can be regarded as a nuisance injurious to health."

Will you kindly say in your next issue—1st, if you think the state of things I have described is injurious to health or not; and 2nd, if there be a nuisance, what further steps should I take in the matter.

Your obedient servant,

Sept. 13th, 1880.

AN OLD SUBSCRIBER.

* * We do not understand whether under the title "health officer" our correspondent refers to the inspector of nuisances or medical officer of health. We apprehend the former is intended; for it seems to us incredible that the medical officer of health should not have seen the complainant and heard his own statement, and it indicate curious notions of duties that even the inspector of nuisances should not have seen the individual who experienced the offensiveness complained of. The question is one which the sanitary authority can best deal with, and we should advise our correspondent to seek an interview with the medical officer of health. If this course fails, however, our correspondent should submit his complaint to the justices under sec. 105 of the Public Health Act, 1875. Even market gardeners are not to be permitted to treat individuals living in houses overlooking their gardens as if they were vegetables requiring to be manured from time to time.—ED. L.

Canadian.—It is not our custom to insert letters such as the one forwarded to us. There can be no serious difficulty in obtaining from a consulting physician the information our correspondent requires.

Mr. Spawforth is referred to a general notice in another column.

SUPRAPUBIC PUNCTURE OF THE BLADDER.

To the Editor of THE LANCET.

SIR,—Mr. Treves' letter on the above subject confirms my statement that aspiration is more troublesome and for some reason more dangerous than puncture. This also, according to my experience, applies to the use of very fine trocars and cannulas (Southey's, I think, they are called) for abdominal puncture. How suprapubic puncture can have been allowed to drop out of use I cannot understand. In some cases it is preferable; in others the only justifiable means of relief. What my advocacy failed to do, Mr. Teevan's will probably accomplish.

Kennington-park-road, Sept. 8th, 1880.

W. J. MARSH, M.R.C.S.

*M.D. (Devonport) and A Candidate (Manchester).—*We understand that the result of the half-yearly examination in Arts &c. for the diplomas of Fellow and Member of the College of Surgeons will be made known in a few days. If successful, the son of "M.D." could commence his hospital studies in October next. Registration is abolished at the College.

*Unlucky Watch.—*The licentiate in question is, in the eyes of the law, only a surgeon. Consequently he cannot also call himself a physician.

*Mrs. Browne.—*There are no published statistics on the subject.

THE LATE MISS NEILSON.

To the Editor of THE LANCET.

SIR,—Since January, 1876, the late Miss Neilson was generally under my care when in London, and I saw her immediately before her visit to Paris. In April, 1876, Sir William Gull also saw her in concert with me, and, as his opinion entirely concurred with that which I formed of her case, it may be of interest for me to offer some observations now that Dr. W. E. Johnston's letter to *The Times* has made the medical features of the deceased lady's case matter of public comment, and has placed in some doubt the treatment adopted by Drs. Mounier and Gantillon, as if that treatment had been in some way responsible for this gifted lady's untimely death. Dr. Johnston's letter, as quoted in THE LANCET of August 28th, contains the following statement:—"The post-mortem examination disclosed the extraordinary fact, one of the rarest in the history of medicine, that in her writhings she had ruptured a varicose vein in the left Fallopian tube, and had died from internal hæmorrhage"; and it will be seen that Dr. Johnston assumes that "her fatal attack was evidently one of her usual attacks of gastralgia, which might have been relieved then, as it often had been before, by a free use of morphia."

1. Rupture of a varicose vein in this locality (abdominal hæmatocele) I have seen in my own experience at least ten times, and I have no doubt that the experience of other physicians will bear me out when I say that Dr. Johnston is mistaken in supposing such a case to be "one of the rarest in the history of medicine."

2. What the post-mortem examination disclosed was simply the fact that she had died from this particular form of internal hæmorrhage. It in no way showed that the poor lady's "writhings" had been anything but the usual and necessary consequence of a large and sudden discharge of blood into the peritoneal cavity. I venture to submit also that the history of her death shows that on this vein giving way she was seized with violent pain and collapse, which for some hours arrested further hæmorrhage; that, on reaction commencing, a fresh gush of blood took place from the lacerated vein, and thereupon that a second fatal attack of suffering and collapse occurred; and I venture to add that there is no ground for the suggestion of any attack of gastralgia in the case, nor for the suggestion that the vein burst in consequence of any "writhings," nor for the *ex post facto* suggestion that the hæmorrhage would have been prevented by "a free use of morphia."

3. When Miss Neilson came under my care in January, 1876, she was haunted and depressed by various suggestions which had been made as to disease of heart and of other organs. On one of the first attacks of dyspeptic colic—not "gastralgia,"—for which I was called, I was urgently requested to bring with me the hypodermic syringe and some solution of morphia, which had previously given her relief. I took with me the articles, but urged her to allow me to treat her in my own way, and not to go on with the morphia. To this she consented, and the results were such that she never again asked me for morphia, and I believe that I never once gave her morphia, although I attended her through many such attacks.

Miss Neilson was a most perfectly organised woman, and neither Sir W. Gull nor myself could discover a trace of organic disease about her. She was as graceful and charming in her own house as she was upon the stage, and she would have enjoyed singularly perfect health but for the conditions under which she lived—conditions which no highly organised and sensitive frame could endure. Day after day there were long and sometimes stormy rehearsals; then the dinner, often with a troop of friends; then a long, heavy performance, and then a supper either at her own house or at the house of some friend and with kindred spirits, with whom time passed quickly. The natural result was brain exhaustion; then dyspepsia; then crudity and colic; then strenuous attempts to fulfil her engagements, more than once only by the help of brandy; then collapse, and certificates of inability to perform. More than once she went to her performance only under my promise to be in a box and visit her between the acts. At this point I could again for a time enforce real, simple food, the exclusion of visitors, and, as she returned to the stage, the expenditure of no strength except in a carriage-drive for air, and in the work which she had to get through in her rehearsals and her performances. I taught her maid how to make beef-tea and other simple, suitable foods in her rooms behind the stage, and upon these she worked well and recovered her health; whereas upon the free use of morphia to relieve pain, and upon brandy to keep her going, she had demoralised her digestive organs, and came to a full stop. The Sunday before she last left London she was apparently in charming health, and as gleeful as a bird. What struck me particularly in observing her character and in correspondence which I had with her about her health, when I was not within reach, was her devotion to the stage; her shrewd, womanly knowledge of the world in matters relating to her own profession; her girlish abandon and gleefulness when with friends.

Yours truly,

JAMES EDMUNDS, M.D., M.R.C.P. Lond.

Grafton-street, Piccadilly, Sept. 2nd, 1880.

*A. G. H.—*The licence of the College of Physicians is recognised as a qualification in Medicine and Surgery by the Local Government Board; but an independent Surgical qualification is required for the Army, and we believe also for the Navy.

*Mr. Benj. Baker, M.R.C.S.—*The profession is so obviously on the side of temperance that it can afford to treat with silence the effusions alluded to by our correspondent.

*J. J. P.—*We cannot undertake the comparison desired.

GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—In the *South London Press* of Aug. 21st is a notice of a meeting of the guardians of St. Saviour's, Southwark, in which Dr. Iliff is reported to have said that an investigation was going on the issue of which would no doubt be a great improvement at Guy's Hospital, and that therefore my letter urging a petition to the House of Commons should be simply acknowledged. What Dr. Iliff stated was so exactly opposed to all the information I had received, that I at once, on receipt of a letter from a member of Guy's staff as to this matter and Dr. Iliff's statement, wrote to him. If you think well, will you kindly print the letter.

"Sept. 2nd, 1880.

"DEAR DR. ILIFF,—I was sorry to see your extinguisher clapped over my desire to help, however humbly, my professional brethren at Guy's, who are being sorely snubbed by lay governors, and to help the cause of the sick poor. As chairman of the committee in a like case of the past, in 1862, when I was publicly appointed to that place by the representatives of the South London parishes, I supposed I had a sort of *locus standi* now, and that I should not be considered to be impertinently intruding in urging the parishes to petition the House of Commons. We cannot but be right in our desire that the profession, educated as it now is, should by its highest members have a strong voice in the management of institutions in which they are the chief executive—more so as there can be no safety for the sick in a divided authority. I thought that, at least, every man in our profession would help to right this mischance; hence my sorrow at your position, apparently in opposition. I believe in what you asserted—a present investigation and a more than probable remedy; that you had been altogether misinformed—that is, if the *South London Press*, usually very accurate, gives your meaning. I have written to a member of the staff, and enclosed the slip report of your words. I have answer dated August 31st, 1880, as follows: 'I know nothing of any present full investigation of the mismanagement at Guy's. I think Dr. Iliff must have been referring to the labours of the committee which sat and reported, and whose report gave rise to all the discussions in *The Times*. Seeing that that report ignored the representatives of the staff upon the main questions, it is hardly to be hoped that it will lead to any great improvement; and, as a matter of fact, I think we are more hopelessly at loggerheads with the governing body than ever. Practically the governing body are riding the high horse, and think they can nurse the hospital without the medical officers. I hope, for the sake of the sick poor, that the public will not endorse this view.'

I am, Sir, your obedient servant,

Polperro R.S.O., Cornwall, Sept. 2nd, 1880.

W. RENDLE.

*R. G. M.—*Ellis's or Godlee's plates; Holmes's or Bryant's Surgery; Kirkes's or Foster's Physiology. See article on Books in our last number.

*Mr. Shirley Deakin.—*The papers are under consideration. The letter is, we fear, too long for insertion in its present form.

PAINLESS TOOTH EXTRACTION.

To the Editor of THE LANCET.

SIR,—What is the best application to the gums for the relief of pain during the extraction of teeth? Will any reader reply?

Sept. 4th, 1880.

I remain, Sir, yours &c.,

J. S.

*Dr. Caldwell, (Wakefield, Ontario).—*The worm was evidently a specimen of the *Strongylus gigas*, the passing of which by the urethra is not unprecedented.

PATIENTS' GRATITUDE.

To the Editor of THE LANCET.

SIR,—"A Village Doctor" is quite right. The practice of giving every discharged patient on leaving the hospital a printed paper, reciting that he or she has been "cured" or oftener "benefited," and desires to give thanks to Almighty God for the same, is wrong in principle, and eminently unfair to everybody concerned, and not the least to the parson. My experience is that it is frequently sent in without the personal appearance of the patient at the service at all, in which he is supposed to "return hearty thanks." It really means an advertisement of the hospital named, with a lively sense of favours to come in the shape of church collections and individual subscriptions. My practice is to take no notice of such papers, unless from my personal knowledge of the patient I believe him to be "truly thankful," and even in such cases it is unnecessary to name the hospital, as it would sound, to say the least, odd to give out that John Brown, having ceased to require the services of Messrs. Jones and Robinson, Surgeons, of Puddletown-in-the-Mud, desires &c.

September, 1880.

Yours &c.,

PARSON.

Mr. H. Marsden.—1. Yes, if the circulation were so free as to cause considerable hemorrhage, but this seems to be doubtful.—2. Supposing the child to be very weak, it might do so.—3. In natural breathing, the air-cells are expanded. Artificial respiration does not, as a rule, so quickly distend the cells.

L.R.C.P.—Abstractly the principal is entitled to both fees; but, as a matter of generosity and taste, we think the fees ought to be divided.

Mr. T. Robinson.—Soon.

QUARANTINE AT ST. HELENA. To the Editor of THE LANCET.

SIR,—I shall feel much obliged if you can spare space in your valuable journal for the following notes of my experience of quarantine at St. Helena.

I lately accepted a medical appointment at this island, and, according to terms, left England on May 28th last in the steamship *Grantully Castle*. During the voyage the surgeon of the vessel reported three or four cases of measles. On arriving at our destination the yellow flag was hoisted, and all personal communication with the shore more or less forbidden. Travelling with a wife and young family, I was anxious to know what accommodation would be provided for us. After two or three hours' deliberation of the authorities on shore, we were conveyed on board an old condemned hulk, as there was no proper quarantine station. A ship's boat was lowered, and after receiving great kindness and sympathy from our fellow-passengers, we were taken alongside the hulk. On boarding, it was found to be just the shell of a rotten vessel, too filthy for any human being, and with no protection from wind and rain. A gentleman with us expressed it as a piece of unwarrantable cruelty to attempt to put us there. I refused to go on board; so another hulk was offered us, a shade better, but again not fit for anyone. The captain was blowing his whistle, and becoming furious at the delay of his steamer, so our baggage was passed up, and we were left alone. We huddled together out of the rain as much as possible in what had been a cabin, but was now a tumbling-down collection of beams, spars, old cabin-doors, &c. With these I protected as well as I could the holes in deck to prevent the children from falling through to the bottom of the hulk. The filth was more than an inch deep, consisting of rotting refuse. On this we had to lie down and sleep, and (as far as the authorities on shore were concerned) without food, water, lights, or any accommodation. The next day we were taken with all baggage to a building with one room, situate in a lonely valley to windward of the town. Here we had to live for fourteen days more. As there was no glass in the windows of the room, and a hole in the roof, we all caught bronchitis. Application was made to the Governor to have the windows reglazed, but without effect.

Now, Sir, my object in sending you these particulars is not to enlarge upon my own troubles in coming here, but to make known to any intending visitors who might think of coming here for their health or pleasure what they may expect if they have the misfortune to be put in quarantine. I maintain that when quarantine is to be enforced for even the exanthemata, proper and decent accommodation should be provided.

Yours obediently,

RICHARD CRESSWELL, M.R.C.S., &c.

Jamestown, St. Helena, Aug. 16th, 1880.

Herr Jander.—We must refer our correspondent to the Students' Number (September 11th) of this journal for full information concerning the University of London. The whole curriculum must be passed through.

Dr. W. A. Harris is thanked.

Mr. Irvine.—Yes, on receipt of Post-office order for 2s. 6d.

QUASSIA POISONING. To the Editor of THE LANCET.

SIR,—In reply to Mr. Maples' remarks concerning a case of quassia poisoning, which was reported in your issue of the 14th ult., I must call his attention to the treatment adopted—viz., brandy by the mouth, and brandy with ether and ammonia by the rectum. I can hardly imagine that in alcoholic poisoning (although the symptoms were almost analogous) treatment by brandy would have done any good, but rather have increased the mischief; whereas in this case its administration per rectum seemed to act most quickly and beneficially.

Yours faithfully,

JOHN D. T. RECKITT,
House-Surgeon.

Newark Hospital, Sept. 7th, 1880.

Dr. J. Broom.—We regret we cannot promise the insertion of the communication.

Medicus.—The Manchester Medico-Ethical Society have issued a tariff of charges.

THE DOSE AND VALUE OF CALCIUM SULPHIDE IN ACNE. To the Editor of THE LANCET.

SIR,—Regarding the letter which appeared in your issue of Sept. 4th by Mr. Squire, I may mention that for upwards of two years I have tried the sulphide of calcium in several cases of acne which came under my treatment, and without any beneficial effect. I generally began with one-eighth of a grain three times a day, and gradually increased the dose to one grain. I have also tried sodium hyposulphite and magnesium sulphite with the same result.

Your obedient servant,

Glasgow, Sept. 9th, 1880.

ROBERT LEES, M.B., C.M.

A Country Physician.—The clinical thermometer seems to be largely used in the United States. The *Philadelphia Medical Times* states there are about eight thousand of such instruments annually sold in America.

Mr. A. Gillett.—We do not prescribe. Consult a registered medical practitioner.

URTICARIA.

To the Editor of THE LANCET.

SIR,—In answer to your correspondent, "H. H. N.," I would suggest to him to try the treatment adopted by me in a case nearly similar to his.

My patient, a young woman, aged twenty-eight, complained of spots occurring on her wrists and forearms, face, and feet. Her face became at times quite puffy, and, in addition, the irritation at the soles of her feet was so distressing to her that she had to wear soft slippers and constantly change her stockings, and rub her feet until the itching passed away. The line of treatment adopted by me was—internally, half-drachm doses of solution of acetate of ammonia, with five-minim doses of solution of arsenic, and a few drops of chloric ether, in water, every four hours; the application of compound tincture of benzoin to the parts affected locally, and bran baths twice daily. This having failed to give relief, after consultation with Dr. Murrell, of Westminster Hospital, the patient was given a wineglass of nettle-tea several times daily; a solution of carbolic acid (1 in 1000) locally, and a bath twice daily, consisting of common washing-soda and water. After a few days of such treatment, the patient improved in every respect, the irritation in soles of feet first disappearing, followed by the loss of swelling in the face, and the spots on the body, which resembled no other skin disease but urticaria.

I am, Sir, yours &c.,

Mount-street, W., Sept. 1880. A. B. KELLY, L.R.C.P., &c.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent, "H. H. N.," who asks for aid in the treatment of the above common but often most obstinate affection, I would advise scrupulous attention to the food used, to find out if possible the origin of the evil, analysis of the urine, the exhibition of rhubarb with bicarbonate of soda, and the free use of spirits of nitre with feather or brush as a lotion on the parts affected, permitting free evaporation. This latter application I have found so useful in many distressing cases of nettle-rash that I would feel indebted to any of my brethren who, after trying it, would communicate the result to me. The articles of diet most likely to produce urticaria are flatfish, coffee, stone fruits, shellfish, bread containing alum, bitter beer, watercress, and edible rhubarb.

Yours faithfully,

Folkestone, Sept. 6th, 1880. S. CLARK, M.D.

Mr. H. Archibald had better put the question to his ordinary medical attendant.

Zeta.—The Secretary is Dr. W. H. Rollins, 12, Beacon-street, Boston, Mass., U.S.A.

THE INFLUENCE OF PEROXIDE OF HYDROGEN ON FERMENTATION.

To the Editor of THE LANCET.

SIR,—I beg to direct your attention to the fact that, while in noticing the recent experiments of M. Regnard, you did not overlook the prior researches of Guttman and Fraenkel, you have made no reference to my yet earlier investigation of the same subject. Some two years ago I addressed a short letter to you in connexion with this matter, and now I must again claim your indulgence to allow me to point out that M. Regnard's results are not in any sense more original than those of Guttman and Fraenkel, and that my investigation, which was the first of the kind, led to the discovery of the antiseptic properties of peroxide of hydrogen. A record of my experiments will be found in the *Chemical News*, Sept. 29th, 1876, and in the *Moniteur Scientifique* for July, 1877, and also in my recently published "Nature's Hygiene" (Baillière and Co.). M. Regnard certainly ought not to be unaware of my prior researches, seeing they were published long ago in a French scientific journal so well known as the *Moniteur Scientifique*.

I am, Sir, yours faithfully,

West Kensington, Sept. 4th, 1880. C. T. KINGZETT.

CORRIGENDA.—One of the works we mentioned last week as worthy of the notice of students in their pursuit of practical physiology was named "Power and Kidd." The little volume we intended to recommend was the "Manual for the Physiological Laboratory," by Dr. Vincent Harris and Mr. D'Arcy Power, published by Messrs. Baillière, Tindall, and Cox.—The number of men in the provident dispensary mentioned by Mr. Bradford in our issue of Sept. 4th, p. 400, should have been stated as 1197, not 1297.—The Scholarship in Human Anatomy at the London Hospital is awarded every year, and the examination for it takes place in March, not April, as stated in our last.

Bradford Observer, Society Times, Pharmaceutical Journal, Westminster and Chelsea News, Scottish Leather-Trader, North-Western Gazette, New York Medical Record, Boston Medical and Surgical Journal, Sanitary Journal, Western Morning News, Western Times, Wandsworth and Battersea District Times, City Press, Seaham Weekly News, Hand and Heart, Indian Medical Herald, Church of England Temperance Chronicle, Science, Egyptian Gazette, Englishman, Daily Free Press, Philadelphia Medical Times, El Observador Medico, Isle of Man Times, Morning Herald, &c. &c., have been received.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir J. Paget, Chipping Sodbury; Sir H. Thompson; Sir T. Acland; Dr. Peacock, London; Dr. Burdon-Sanderson; Dr. Dyce Duckworth, London; Mr. Barnard Holt, London; Mr. J. Gant; Mr. G. Fleming, London; Dr. Atkinson, Kingston; Dr. Wise, London; Dr. Redwood, Rymney; Mr. Dyer; Mr. Bradford, Smethwick; Dr. Gee, London; Dr. Bantock, London; Rev. J. Rodgers, London; Dr. Milne, Shipham; Dr. Broom, Clifton; Mr. C. T. Kingzett; Messrs. Dalziel Brothers; Mr. Cresswell, Birmingham; Dr. Clark, Folkestone; Mr. Reckitt; Mr. D. D. Jones; Mr. Wood, Isle of Man; Mr. Hopkins; Dr. J. S. Stocker, London; Dr. Annington; Mr. Ewart, London; Mr. Palmer, London; Dr. Muter; Mr. Macdonald; Mr. Rendle; Messrs. King and Co.; Mr. J. Startin, London; Mr. Gillett; Dr. Tatham, Salford; Mr. Macdonald, Braco; Mr. Marsh; Mr. Shirley Deakin, Allahabad; Messrs. Oliver and Boyd; Dr. Finch; Mr. May, London; Mr. A. B. Kelly; Dr. Pitta, Funchal; Mr. Baker, Brentwood; Mr. Statham, London; Dr. Caldwell, Lakefield, Ontario; Mr. J. S. Ward; Mr. Hayden; Mr. Fancock, Norwich; Mr. Furlong, Lynton; Dr. Peters, Davos; Mr. R. Lees, Glasgow; Mr. Irvine, Mr. Hill, London; Dr. Spencer, Bath; Mr. Scott, London; Herr Jander; Dr. McNeill; Mr. Dyer; Mr. Stedman, Newport, R.I.; Mr. J. Brown, Leeds; Dr. Walker, Putney; Mr. Philip, Alexandria; Mr. Bert; Dr. Harris; Mr. Moore, Jersey; Dr. Packman, Hertford; Mr. Reed; Dr. Sayer, Earls Barton; Mr. Bloxham; Mr. Bentley; Messrs. Dick, Radcliffe, and Co.; Mr. Hoggood, Chipping Norton; Mr. Crisp; Mr. Forbes; Mr. Oldfield, Ashill; Mr. Stewart; Mr. Cox, Williton; Mr. Young; Mr. Watson; Mr. Dunn; Mr. Horsfall, Leeds; Mr. McKeown, Belfast; Messrs. Fannin and Co., Dublin; Dr. Athill, Dublin; Mr. Jackson, Liverpool; Mr. Gulliver, London; Mr. Stillard, Birmingham; Mr. Pitts, London; Mr. Bennett, Marsden; Mr. Walker; Rev. W. S. Mundon; Mr. Scott, Halifax; Messrs. Wright and Co., Birmingham; Mr. Crespi, Stroud; Mr. Eager, Melton; Mr. Holmes, Maidstone; Messrs. Bingham and Co.; Mr. Maclehoose, Glasgow; L. E. P.; Verbens; M.B.; Caius; Phys.; Canadian; Unlucky Watch; L.R.C.P.; A. G. H.; R. G. M.; Parson; J. S.; J. J. P.; F.R.C.S. Eng.; J. W. S., Aberdeen; Medicus; Veritas; &c. &c.

LETTERS, each with enclosure, are also acknowledged from—Mr. Legge, Derby; Mr. Nicholls, Hartest; Mr. Jones, Stratford; Mr. Johnston, Corby; Mr. Skinner, Shrewsbury; Dr. Ryley, Stratford; Mr. Cuckson, Gainsborough; Mr. Newman, Bowness; Mr. Tylecote, Sandon; Dr. Moreton, Sheffield; Mr. Corbett, London; Dr. Barnett, Rochester; Mr. Macgregor, Huddersfield; Mr. Reid, Canterbury; Mr. Thomas, Brecknock; Mr. Schoth, London; Mr. Hyatt, Stow-on-the-Wold; Mr. Tarleton, Cheddar; Mr. Sykes, Hackney; Mr. Moore, London; Mr. Bloxham, Littleborough; Mr. Robbins, Buxton; Mr. Ramsden, Ravensthorpe; Mr. Heywood, Manchester; Mr. Spencer, Glasgow; Mr. Hallas, Halifax; Mr. Callard, London; Dr. Prior, St. Albans; Mr. Ravenhill, Aylesbury; Dr. Waters, Liverpool; Mr. Armstrong, Newton Abbott; Mr. Taylor, Bocking; Mr. Shearman, Rotherham; Mr. Christy, Stafford; Dr. Wilson, Tunbridge; Mr. Whitley, Leeds; Mrs. Byrn, Weston-super-Mare; Mr. Cappe, Brookwood; Mr. Robson, Leeds; Dr. Meedham, Gloucester; Dr. Williams; Rev. NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.

The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

Lectures ON

THE RELATIONS OF SARCOMA TO CARCINOMA.

Delivered at the Royal College of Surgeons in June, 1880,

By HENRY TRENTHAM BUTLIN, F.R.C.S.,

ERASMUS WILSON PROFESSOR OF PATHOLOGY TO THE COLLEGE,
ASSISTANT-SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, &c.

LECTURE II.—PART I.

SUBPERIOSTEAL TUMOURS OF BONE.

MR. PRESIDENT AND GENTLEMEN,—The elaborate papers on "Sarcoma of the Long Bones" which have recently been published in the *American Journal of the Medical Sciences*,¹ based on a study of so large a number as 165 cases, and issuing from the pen of one of the ablest American surgeons, wellnigh deterred me from carrying out the project I had already formed of making sarcoma of bone the subject of some part of the present course of lectures. But on deliberation, I determined to adhere to that which I had purposed; for, in a subject so extensive, and possessing so many and such important bearings, even a study of the views now generally held would in itself be interesting. Such a study would not, however, as I think, fulfil the intention which your learned Committee had in view when they considered the scope of this professorship, and assigned to it its limits. Bearing in mind their design—the encouragement of original pathology,—I have employed the work of others only so far as may be necessary to enlarge or illustrate my subject; and have sought to combine and analyse the material at my disposal in such a manner as may serve perhaps to elicit some new fact or strengthen already existing views, and always in the hope of affording new material for the thought and work of others.

In the consideration of sarcoma of bone, I shall differ from Professor Gross in including sarcomas of all bones, with one exception—the upper jaw, the tumours of which are often of uncertain origin; and from almost all authors in placing the various tumours collected together under the generic term "Osteoid," each in the group to which the cell-growth which forms its basis appears naturally to refer it. In accordance with the general plan of division of tumours laid down yesterday all primary malignant tumours of bone must be regarded as sarcomas. For no epithelial elements exist normally in bone. The hard parts, the cancellous tissue, medulla, nerves, bloodvessels and lymphatics, even the endothelial lining of the vessels, belong to the connective-tissue series. The tumours which grow from bone must therefore be connective-tissue tumours, not carcinomas, and the presence of an alveolar structure, if decidedly impressed, can only serve to inspire a doubt if such a tumour be really primary. The subject, thus simplified, would still be very complex; but, happily, it is capable of division by an easy and natural method. I mean by separate consideration of the tumours of central and those of superficial origin. I shall speak of them throughout as central and subperiosteal; for although the latter are more probably of periosteal than of osseous origin, the term "subperiosteal" will serve to distinguish them from tumours growing from the outer surface of the periosteum, which will not be included in the present study. Of most tumours it is easy to decide the origin; but tumours which have attained a large size, and have by their growth destroyed much of the structures in whose midst they lie, the difficulty is often insuperable. The presence of a thin, bony shell surrounding the tumour, or the maintenance of the outline, however much thinned and softened, of the cortex through it, its position, shape, the relation of the periosteum to the bone at its extreme limit, are points to which the attention is sure to be directed in a doubtful case. Where these guides fail the case had best be laid aside as useless, or unsafe for purpose of comparison.

The subperiosteal sarcomata may be all arranged under three heads—(1) round-celled, (2) spindle-celled, and (3)

mixed-celled sarcoma. The round-celled and spindle-celled require no further definition than that which applies to such tumours wherever they occur. The first consist of vast numbers of round cells, generally of equal or nearly equal size, and bearing similar characters, embedded in a homogeneous or granular basis substance, often fibrillated or distinctly fibrous, or maybe calcified or chondrified, or even ossified, in parts. With these are associated the finely-reticulated tumours whose structure resembles that of a lymphatic gland, which have on that account received the name of "lympho-sarcoma" or "lymphadenoma"—a name to which their structure perhaps entitles them, even when their relation to adenoid or lymphatic tissue cannot be proved. In the second group all the other conditions may be those prevailing in the first, but the type of cell is altered. It is no longer round or oval, but is narrow and elongated. Although by courtesy these cells are all called spindle-cells, many of them are fibre-like or oat-shaped, or look like grains of wheat. As in form, so in size, the difference is striking, the cells of one tumour comparing as a race of giants with the pigmy forms belonging to another.

There still remain many tumours which, by reason of the various forms and characters of their cells, can neither be included among the round nor spindle-celled sarcomas. Not only in different sections of the same tumour, but in different areas of the same section, or even in the different parts of the same field of the microscope, may be discerned round, oval, elongated, spindle, and stellate cells, or the soft parts of a tumour may be formed of round and spindle, or of oval and stellate cells. Of these more complex tumours I have thought fit to make one separate group; not because they present precisely similar characters, but because they possess characters in common, which unite them more closely with one another, than with the tumours of either of the other groups. The presence of bone or lime salts or cartilage does not render a tumour mixed celled. The practice so universally adopted of classing together all tumours, large portions of which are ossified or calcified, and considering them as one common group, because they are so ossified or calcified appears unworthy of our present knowledge. The soft tumours are grouped according to the form of their cells; but hard tumours, or those which possess a hard base, are grouped together without reference to their more essential characters, as osteo- or osteoid sarcomas, or osteoid cancers, or osteoid chondromas. The term osteoid is singularly open to objection. It implies the presence of a substance like bone, yet not bone. Its use should be restricted to tumours which are calcifying; which present when macerated large, white, hard, chalk-like masses. But it is employed equally to designate those which are ossifying, which contain true bone. An osteoid cancer or sarcoma is, then, a sarcoma of bone which is either ossifying or calcifying. That is, the word osteoid is used to denote the presence of bone and of a substance like bone. If we could not distinguish between these two substances there would still exist a reason why we should call these tumours osteoid. But we can distinguish whether a sarcoma is ossifying or calcifying, therefore there is no reason why we should not call it an ossifying or calcifying sarcoma. Indeed, there is every reason why we should do so, and why we should discard a term which is unnecessary, and is often used inconsistently.

Again, an osteoid chondroma should be a tumour composed of cartilage but like bone. An osteoid chondroma, however, is usually a sarcoma, many parts of which are transformed into a substance in some respects resembling cartilage, or, rather, resembling the animal basis of a rough kind of bone after its earthy salts have been removed. If it were impregnated with earthy salts it would be true bone, and would cease to be cartilage. But it contains no earthy salts and is therefore not osteoid, at least in the same sense as an osteoid sarcoma or cancer is said to be osteoid. It is in truth a chondrifying sarcoma. The term osteo-sarcoma is on some accounts more objectionable than osteoid sarcoma. It may mean a soft sarcoma of bone or a sarcoma growing in the interior of a bone or a sarcoma which contains bone, and which grows either from a bone or from the soft parts. It is employed by different authors in all these different senses. It is therefore worse than useless, for it may mislead. To all these terms the same objection may be raised. They are not employed always in the same sense or to express the same condition. They are employed inconsistently, and are therefore mischievous.

Nothing is easier than to criticise or attack existing customs and institutions, but he who would destroy should

¹ July, 1879, p. 17. Professor Gross.

in honour be prepared to replace them by others which can be shown not only to be newer, but better adapted to the particular purpose for which they are to be employed. I have, however, no new nomenclature to propose, for with the exception of the word "mixed-celled," which appears unavoidable, I have introduced no new term into the nomenclature of bone sarcomas. But I desire that as the simple sarcomata of bone are classed according to the form of their cells, and as little difficulty is experienced in assigning to each its place, so may the more complex tumours which contain bone, or earthy salts, or cartilage, be classed according to the form of the cells which compose their softer parts. It is by the transformation of these softer parts that bone and cartilage are formed, and by the increase of these softer parts the increase of the mass takes place. If particles of bone, or lime, or cartilage are scattered through the tumour, no modification of its name seems needful. But if a large proportion of these tissues should occur so that the characters of the tumour are materially altered by them, this alteration may be expressed by some appropriate term preceding that which applies to the tumour, on account of the form of its cells. For example, this tumour, which consists partly of dense, hard substance, partly of soft succulent material, is a calcifying spindle-celled sarcoma, for the succulent material is formed of spindle cells, and the hard substance is impregnated with earthy salts, but there are no lacunæ or canaliculi. Again, this tumour, which presents to the eye characters almost identical, is an ossifying mixed-celled sarcoma, for the succulent material is formed of mixed cells, and the hard substance has the structure of the rough bone common in such tumours. A nomenclature such as this is sufficiently simple and easy of application. Of fifty-six cases of subperiosteal sarcoma, of which the accounts are sufficiently complete, twenty-two were round-celled, eighteen spindle-celled, and sixteen mixed-celled. The bones affected by them were—the femur in twenty-one instances, the skull and the tibia each in nine, the humerus in five, pelvis and lower jaw each in three, the clavicle and fibula in two, the ulna in one, and ribs in one. The relative proportions are probably approximately correct for all bones except the pelvis. But the number of tumours of the pelvis, especially of the sacrum, would be greater were it not for the extreme difficulty of deciding whether their origin is central or superficial.

Were I to follow the ordinary method of describing these subperiosteal tumours, I should write a separate account of each of the three groups of sarcoma in its relation to the bones, should state what bones it most commonly attacks, what is the manner of its growth, what its characters, its progress, duration, and its termination. But I think we shall gain a better knowledge of them if we employ a more tedious, but perhaps more useful, method of investigation, and study their characters and the conditions of their existence in each particular bone which they affect.

The femur is of all bones by far most frequently affected by subperiosteal sarcoma. It is subject to all three forms, and apparently to all three nearly in the same proportion; for of twenty-one cases five were round-celled, eight were spindle-celled, eight mixed-celled. The five round-celled sarcomas all grew about the lower third or lower epiphysis. They attacked patients, four of whom were males, varying in age from sixteen to twenty-seven years. Of three a squeeze or blow was the cause assigned; all were most rapid in their growth. Only one affected the lymphatic glands. In four amputation was performed, and in neither of the four was there recurrence in the stump. One of these patients recovered from the amputation and remained well after a period of fourteen months.

But thus to analyse in numbers each sub-group of tumours would weary you, and waste time which might more profitably be employed. I have therefore had these tables prepared, from which many of their more important characters may easily be read, and shall content myself with explaining what may seem to need explanation, with pointing out analogies and distinctions, and with supplying so far as possible the deficiencies which cannot but exist in tabular analyses.

Of these five cases only No. 1 was permitted to run its natural course. The tumour was a large chondrifying and calcifying sarcoma in a woman, twenty years of age. No operation was performed, and eight months after the first appearance of the growth the patient fell a victim to the disease. The tumour never ulcerated, but secondary tumours formed in the integument of the abdomen and axilla; and

after death the lungs and kidney were infiltrated with new growths, some of which, like the primary tumour, were calcified. Although amputation of the thigh was performed on No. 2, the operation can scarce be thought to have changed the course which the disease would naturally have run. Seven weeks after the operation the patient sank and died from a generalisation so extensive that I have no parallel case. The calvaria, sternum, heart, lungs, liver, kidneys, and inguinal glands were all the seat of secondary growths. And as the primary tumour was a blood-cyst, so were the growths of which it was the parent soft, easily broken down, and black with blood. The whole duration of the disease was only fourteen or fifteen weeks.

Of these five cases three were such as would generally be termed osteoid, and would therefore be classed separately from the softer tumours. But the most careful study fails to discover that they possess in common any characters except their bony structure, which distinguish them from tumours which contain no bone.

Of the eight cases of spindle-celled tumours, three affected the diaphysis, and five the lower third. The subjects of them ranged from nine to forty-one years old. The growth of all was rapid, the issue fatal. But death in three was due directly to the operation which had been practised for their relief. Though only one case was not submitted to operation, three may be considered to have run an almost natural course. On No. 6 an amputation at the hip was followed by the appearance of tumours beneath the skin in various regions, and in six months by death. But a more accurate account, together with the post-mortem examination, could not, unfortunately, be obtained. No. 9, whose tumour contained bone and cartilage, died from amputation of the hip; but had she survived the operation, the period of a year, during which the tumour had existed, could only have been extended for a short space longer, for secondary growths were already disseminated through both lungs.

In No. 11 many characters of the disease are so well exemplified that the case deserves more ample record. The patient was a married woman, twenty-seven years of age, under the care of Mr. Callender. The tumour had commenced a year before her admission to the hospital high up in front of the left thigh. Its growth, which had been slow at first, had latterly attained a fearful speed. It formed a smooth, elastic, almost fluctuating mass, but little painful, and not hot, the integument covering it dusky, oedematous, and traversed by large and tortuous veins. The whole thigh was occupied from the groin almost to the knee. Until her death, two months later, she remained an inmate of the hospital. During this time the tumour continued to increase in size, and the groin glands became enlarged, but the skin remained unbroken to the last. The autopsy discovered an enormous, brain-like growth, springing from the bone whose upper part was bare and rough. The periosteum was destroyed, and the tumour, infiltrating the surrounding muscles, passed up beneath the pubic arch into the pelvis and abdomen. There spreading, it attacked the bladder and the iliac veins, penetrating the walls of veins and viscus. The inguinal, pelvic, and lumbar glands were enlarged and sarcomatous, and both lungs were filled with growths. The cells which composed the tumours were rather oat- than spindle-shaped, and presented a singular uniformity in size and shape. In its continuous growth, infiltration of the surrounding structures, absence of ulceration, but secondary affection of the lungs, this tumour presents all the characters we may expect to find in a spindle-celled sarcoma of the femur. Only in one important respect does it differ from all the tumours of the same sub-group. The lymphatic glands were full of the same brain-like substance as that which formed the tumour. It may be that this rare event was caused by a continuous infiltration of some of the femoral or inguinal glands, and that from these the affection spread along the unwonted channel until gland after gland was transformed into a malignant mass.

Only in two cases was there recurrence after amputation. No. 7 and No. 13 were both females, and of nearly equal age. The former suffered amputation through the thigh for the removal of a tumour which had been three months growing, and had not yet attained a formidable size. It proved to be a brain-like mass, but broken down and mixed with semi-clotted blood—a form of the old fungus hæmatodes. Three months later she returned with recurrence in the stump, and disarticulation of the hip was practised. The second tumour, like that of which it was a recurrence, was full of black and semi-clotted blood. The patient rallied

from the operation, but in a few days began to sink, and in three weeks died—apparently not from the amputation, for the wound was wellnigh healed, but from affection of the lungs, of which symptoms had lately been evinced. The tumour for which amputation was performed on No. 13 was a calcifying and chondrifying growth, which had already existed for a year—a longer time, by full four months, than the whole duration of the former case. It seems to have been recognised after the amputation that a portion of the disease still remained in the medulla of the femur, but it was not till six months later that the new growth was actually observed. A year after the amputation of the thigh a second amputation was performed at the hip-joint, and a year after the second operation the patient died with huge masses of secondary growth in the lungs and pleuræ and three small tumours of the lining membrane of the heart. These two cases are so similar that there are only two characters in which they manifestly differ—first, in the duration of each stage of the disease, and consequently in their whole duration; second, in the nature of the tumours. The more slowly growing was composed largely of cartilage, or was calcified; the more quickly growing of brain-like vascular tissue, whose consistence was so soft and vessels so weakly walled that more than half its bulk was composed of semi-clotted blood. It is impossible to refrain from associating the greater density and hardness of the one tumour with its slower growth and late recurrence, the greater vascularity and softness of the other with its far more rapid development. This impression is, however, speedily, and perhaps happily, corrected by the instance of another tumour equally dense and hard (No. 9), a chondrifying and ossifying sarcoma. Amputation was performed in this case also when the tumour had endured a year. But when, a few days later, the patient died, both lungs were partly filled with growths of a like nature and consistence.

The cases of *mixed-celled* sarcoma occurred in patients from thirteen to thirty-eight years old. Seven affected the shaft, one the lower fourth. Only two (Nos. 15 and 21) pursued an uninterrupted course. Of both the duration was equal. In both the lungs were the seat of secondary growths, but in one the popliteal, lumbar, bronchial, and tracheal glands were also so transformed by the disease that they retained no trace of normal structure. In its implication of the glands this tumour stands alone among the mixed-celled sarcomas of the femur. Nor is it easy to understand the relation which this glandular affection bore to the tumours of the femur. It may be that the popliteal glands were involved in its continuous growth. But the natural condition of the femoral and inguinal glands and the diseased condition of those of the abdomen, render it more probable that, as in most cases of sarcoma, so in this, the blood- and not the lymph-vessels were the channels by which the infection was conveyed.

Recurrence in the stump took place in one patient, No. 16, whose tumour, a huge mass containing many cysts or cystoid cavities, grew almost to the hip-joint, where amputation was performed. No. 14 deserves notice for the rapidity with which it spread, and, within three months of its first appearance in the thigh, filled the lungs with numerous tumours like itself. The date of its origin is almost indisputable, for the patient, a boy of fourteen years, while in what appeared to be good health, received a severe blow on the thigh from the handle of his cart on the 5th of November, 1872. The part at once began to swell, and so rapidly increased that in eight days from the injury he was unable longer to pursue his work. On the 3rd of February, 1873, he died immediately after amputation of the hip. The tumour ossifying, chondrifying, and hollowed out by large cavities filled with clear yellow fluid, surrounded the whole femur from the condyles to the lesser trochanter. Of these mixed-celled sarcomas the first four contained cavities of a similar nature, for the most part ragged and cystoid rather than cystic. And each of these four tumours was partly cartilaginous; two facts which I mention together because the second may perhaps help to explain the first, for the tendency of cartilage to soften down to a viscid or even thin clear fluid has long been recognised.

Let me also draw attention to the frequency with which bone or cartilage, or both, occurred in mixed-celled tumours of the femur. And let me at the same time point out that these ossifying or chondrifying or calcifying tumours present no other characters in common which entitle them to be classed together, and no characters which separate them from the remaining tumours of the sub-group.

Clinical Retrospect

OF A

HALF-YEAR'S HOSPITAL WORK,

BY MATTHEW CHARTERIS, M.D.,

PROFESSOR OF MATERIA MEDICA AT THE GLASGOW UNIVERSITY, AND
PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY.

PART II.

THE various forms of heart diseases and murmurs were well illustrated by twenty-nine selected cases. There were seven cases of hypertrophy, one of which died. Here the organ was found nearly twice its normal weight, the increase being chiefly in the left ventricular wall. There was no valvular disease, and doubtless the hypertrophy was related to the kidney complication which had preceded the heart's increase.

Of three cases of pericarditis one died. There were two well-marked cases of mitral obstruction, the peculiar thrill, the limited area, and the presystolic character of the murmur being easily differentiated.

Of the more common valvular lesion of mitral regurgitant there were ten examples, and of these one died.

There were seven cases of aortic obstruction and aortic regurgitant, and of these two died, and post-mortems were permitted, which revealed narrowing in the one case, and patency of the valve in another. There was one case of intra-thoracic cancer, diagnosed as such during life, and verified after death. The symptoms were a husky voice followed by paralysis of left vocal cord, dulness on percussion at the base of the lung, and rapid emaciation. No red-current jelly appearance was presented by the sputa.

One case of diabetes mellitus died within forty-eight hours after admission, and an opportunity was afforded for a post-mortem examination. Nothing noteworthy was detected, although Dr. Foulis made a very diligent and accurate inspection of all the organs of the body, special attention being directed to the brain. Nothing confirmatory of Dr. Dickinson's views was observed. Previous to death the patient fell into a somnolent condition, the urine being passed involuntarily, and the breathing being stertorous. The conditions were similar to those noted in uræmia, but without the muscular twitchings and preceding headache. One diabetic patient was dismissed as irregular. The others were placed on an entirely new method of treatment, for the carrying out of which, and for many practical suggestions, I have to express my gratitude to my able and esteemed pupil and friend, Mr. Edmund A. Cook.

The plan adopted consisted in the administration of pilocarpin on the lip in 1-20th grain doses thrice daily for a fortnight. This relieved the distressing dryness of the tongue, and consequent thirst. The pilocarpin was followed by a course of the mixed phosphates—viz., of fresh bone-ash of femur, light calcined magnesia, bicarbonate of potash, phosphate of soda, syrupy phosphoric acid and water.

The cases will be reported in some subsequent paper more fully. It may, however, here be observed that the success was very striking. The urine diminished from 300 to 90 ounces, weight was regained, and the patients were enabled after four months' residence in the hospital to resume an out-door occupation. One of the diabetic patients was kindly transferred to my care by a colleague in whose wards he had been for three months without advantage either in regard to the general health or the diminution of urine. Placed upon the treatment mentioned there was decided improvement, and at the time of writing this the urine has lessened in quantity from 250 ounces to 120, and at this last point has remained stationary for some weeks.

A young woman, nineteen years of age, was admitted into the wards in a very critical condition. While waiting her turn to be examined in the out-patient department she was suddenly attacked with vomiting of blood, so copious and so exhausting that instant death seemed imminent. Ergotine was at once injected, and with excellent effect, for it seemed to stay the bleeding, and the circulation, as evidenced by the pulse, was restored in a few minutes after its administra-

tion. The ergotine was subsequently followed by gallic acid in four-grain doses every two hours for a night and a day, when all medicinal treatment was abandoned, and a carefully regulated dietary was put in force. This consisted of beef-tea injections thrice daily for nine days, while only a very little iced brandy-and-water was given by the mouth. When the thirst was excessive she was permitted to suck ice alone, but on no account was she allowed to raise herself in bed. After the ninth day an occasional teaspoonful of essence of beef was given, followed on subsequent days by milk, and, as convalescence became apparent, by dry toast. To combat the anæmia dialysed iron was also ordered. In other four cases of gastric ulcer, diagnosed by the localised pain, by the history of hæmatemesis, and by the weak, bloodless condition of the patients, the same line of treatment was adopted, and in every case with satisfactory results.

For a well-marked case of cancer of the stomach, recognised to be such by the presence of a tumour, the cancerous cachexia, and by the age (forty-five), only palliative means were employed, as Chian turpentine had not in the early part of the session come into vogue. Of three cases of acute peritonitis, two recovered; the treatment being by the calomel and opium pill. A case of lead, and another of carbonic-acid, poisoning, made good recoveries.

Of intestinal parasites there were four examples, two being those of tapeworm, and for these the usual remedies of oil of male fern, followed by castor oil, succeeded in dislodging many yards of the worm. The head, although carefully searched for, was not detected. For the two cases of ascaris lumbricoides santonin was given, and caused, as it frequently does, the expulsion of the parasite, although this was attended by great sickness, griping, and prostration.

Opportunities were afforded for the diagnosis of twenty cases of hepatic disease, including congestion, cirrhosis, cancer, jaundice, catarrh of bile-ducts, and gall-stones; and post-mortem examinations were made showing the characteristic appearances of cirrhosis and cancer of the organ.

A case of Hodgkin's disease, or lympho-sarcoma, terminated fatally, although arsenic, according to the suggestion of Billroth, was given in large and increasing doses. Death was preceded by a temperature of 103° for four days with profuse perspiration. In the preceding session there were three typical cases of Addison's disease, but this year there were none.

The treatment pursued in eleven examples of chronic Bright's disease with dropsy has been generally indicated in the previous part of the paper. In seven cases of the acute variety the treatment consisted in dry cupping over the loins, drastic cathartics (notably elaterium), and milk diet. Dr. Charteris said that experience in past years warned him against resorting to the induction of perspiration by artificial local means, such as hot air or warm bricks, in the acute form of nephritis. He had seen great distress occasioned and rise in temperature in all; while in two cases he distinctly attributed the supervention of uræmic convulsions to their persistent employment.

Diseases of the nervous system always bulk largely in hospital practice in Glasgow, and doubtless many patients are sent in because the friends are anxious to be spared the fatigue and expense attendant on careful nursing. Some of these are well worthy of observation during life; and it is greatly to be regretted that the after-death appearances cannot be observed, through the prejudice and ignorance of the relatives, exhibited in negating, as they term it, the "opening of the body." Much valuable information is thus lost which might be conveniently utilised.

Without entering into details in all, Dr. Charteris said that out of fifty cases of what might be termed diseases of the nervous system, including acute meningitis, hemiplegia, paraplegia, locomotor ataxy, sciatica, lumbago, pleurodynia, epilepsy, chorea, hysteria, and delirium tremens, a few deserved special notice.

Great interest was attached to a paraplegic female, aged twenty-six, who had been transferred to the medical from the surgical wards nine days after an operation for malignant sarcoma of the upper jaw. A localised redness over the sacrum was detected, and, notwithstanding the most careful nursing and the employment of all known remedial means, it deepened into a purple hue, and finally became black. As this result could not be attributed in any way to the persistent pressure which causes an ordinary bed sore, the attention of the class was directed to it as being "the acute decubitus of Charcot," and the fatal nature of the malady,

thus painfully and prominently illustrated, diagnosed. The friends were told of the opinion entertained, and they naturally desired she should be removed home. She died three weeks afterwards. The sore at the time of her dismissal could be covered by the palm of the hand, but it afterwards assumed more ghastly proportions; and death was attributed directly to it, and its production to the carelessness of the hospital attendants. A prolonged inquiry, extending over months, followed, and ended in the withdrawal of the charge. It is needless to say that this inquiry need never have been made had the authorities known anything about the opinion entertained and the medical treatment adopted while in the ward, and the significance attached to bedsores generally and this form of bed sore in particular, as recognised by recent important pathological observations. This information was offered, but refused. A coroner's inquest would have spared much trouble, and presumably would have enlightened official advisers.¹

Hydrophobia, if it can be called a nervous disease, claimed two victims, who came from the same part of a neighbouring county. Pilocarpin was the remedy employed in both cases, and in the first case it was at one time hoped that the trial would have justified its selection; for the patient was a muscular athlete, tall, strong, and wiry, whose constitution was unimpaired by previous illness, and who had, as he said, "neither tasted drink nor smoked tobacco in his life." The drug lowered the temperature, promoted copious salivation and perspiration, and strange to say, the inability to swallow was entirely removed, and the gloominess that hung over the patient at first was succeeded by wild bursts of delirious joy, with fanciful pictures of happiness and peace. The struggle, fierce and terribly violent, which lasted four days, seemed to exhaust the man, and without convulsions and without terror he sank and died.

The clinical record of this case after it had been decided to try pilocarpin is as follows. At 9.45 A.M., when first seen, his pulse was 150 and his temperature 102.6°. One-third of a grain of pilocarpin was injected, and in about three minutes afterwards he began to hawk and spit profusely, and this was followed by a copious perspiration. At 11.15 the injection was repeated, causing the same symptoms, and when seen at 12, he was lying comparatively quiet, and "sweating awfully," as he said. His temperature had fallen to 101°, fully a degree and a half. His pulse being 140 at 2 P.M., the reduction of temperature was more noted, as it was 100° and his pulse was 130. At 4 P.M. he complained of severe pain in the back of his head, for which a poultice was applied. He now asked for a drink of milk. The nurse steadied his hand and assisted him to bring the cup to his head; when it was there, he threw the milk into his mouth as a man might do a pill, and swallowed it with a great gulp. After he had done this, he rose to his full height in bed and said, "I have swallowed at last. I am a cured man. I'll go home to-morrow; but don't mind me, don't mind me, when I get out." Everything was done to foster the idea that he was getting better, and he promised money and the eternal gratitude of himself and family, adding, "The vale of Leven will wonder when they see me back a cured man." At 6 P.M. pilocarpin was repeated, but the result was not the same as before, for little perspiration was induced, but instead copious micturition. His temperature had again risen to 102°, and his pulse was 160. At 9 P.M. his condition with regard to temperature and pulse was unaltered, and he talked incessantly. Bromide of potassium was given in large doses, but no sleep was obtained. At 9 A.M., when again seen, he said he had not slept, for men had come in and sat on him, bruising him much all down the back. His temperature was 102°. Pilocarpin was again injected, but little perspiration was induced. At 12, three hours afterwards, pain was experienced over the kidney, and a trace of albumen detected in the urine. He saw his wife at his own request, and to show her he was better, he took some milk with an effort, but no particular spasm. He had taken in all since his amendment two pots of Brand's essence of beef. At 4 P.M. the nurse stated he had dozed about ten minutes at a time, but he had had no sound sleep. He appeared much excited about being beaten. Later on he slept about an hour after having an egg beat up

¹ In connexion with bedsores, I have to record that the woman with Erb's spastic paralysis was recently, at my request, readmitted into the ward. She had a large sloughing sore, which was easily treated; but after she had remained a month she found, to her astonishment, that she was pregnant, and, so far as can be judged, she has now advanced to about the fifth month. The paralysis remains *in statu quo*.—M. C.

with brandy, and on awakening he took a slice of bread soaked in water and some essence of beef. During the remainder of the day and the following morning he was simply exhausted through constant talking and want of sleep, but he could swallow easily. At 9 A.M. he wished to go out, and actually reached the door, but was persuaded to return. His exhaustion was very intense, and the albumen in the urine very abundant. At noon of the same day he died.

Thinking that perhaps the pilocarpin had not been pushed sufficiently actively in this case, in the next it was given at short intervals, and with beef-tea injections. The struggle was, however, shorter here, for within forty-eight hours of his admission the man succumbed. It is peculiar as showing the nature of the disease to state that in the first case there was a thorough and intelligent appreciation of what it was; while in the other there was neither wonder nor anxiety, or even, so far as could be learned, any knowledge that the disease was hydrophobia, or that a bite received three months previously had any connexion with the ailment for which he was admitted. Dr. Charteris said that his experience now of three cases under his immediate care, and of two others which he had seen, led him to call the disease "pantophobia"; for dread of everything, from the tiniest draught of air to the most carefully muffled footstep, was as significant as the undoubted terror inspired by the thought or the sight of water. The post-mortem, conducted by Dr. Foulis, and the microscopic observations subsequently made by him and Dr. Middleton, revealed nothing which cannot be observed in any nervous disease attended with great excitement and followed by rapid death—such, for instance, as acute mania or delirium tremens. These investigations will be published. The bite in the cases mentioned was in the fleshy part of the hand, between the thumb and forefinger, and the dogs that caused the injury, so far as can be accurately ascertained, were retrievers.

Four cases of chorea were treated by arsenic in the form of Fowler's solution, given in doses varying according to age, from four to eight drops. Improvement was observed about the eleventh day, and the system was thoroughly free from the malady in four weeks, when the constitutional effects of arsenic were manifested. Cod-liver oil, iron, and a generous diet formed the after-treatment of the patients elected to remain in the infirmary. Two girls of the age of fifteen happened to be admitted with the disease on the same day and were placed in contiguous beds. One was a severe case, the other was mild. After a few days it was observed that the malady in the latter was greatly aggravated, and that she was rapidly becoming worse instead of better. This was attributed, and rightly, to the peculiarly imitative character of chorea, and the patients were separated, one being placed in a private room. This precaution was amply justified by the amendment which ensued. In almost every case of chorea, if carefully investigated, the cause is found to be "fright," although this, on an inquiry, may not be obtained from the patient, but from the mother and other relatives. In Dr. Charteris's wards for the last three years all other drugs have been abandoned, and arsenic has alone been trusted to.

Numerous cases of skin diseases were treated, including erythema, eczema, rupia, ecthyma, sudamina, herpes (labialis and zoster), psoriasis, lupus, scabies, and tinea sycosis. Of psoriasis there were nine examples, and in these chrysophanic acid ointment (one drachm to the ounce) was alone employed. In two of the cases the disease was not confined to its usual sites, but completely covered the body, literally from the crown of the head to the soles of the feet. The peculiar and specific action of the ointment was very gratifying, and in an age of medical scepticism marks an epoch of therapeutic success. A singular circumstance was noted—viz., that the acid rubbed in must have some constitutional action, for if applied only to one side of the body it seems eventually, though more slowly, to remove the scales from the other. This observation, although true in one case, was not so marked in the other, and would require further verification. Generally speaking, in psoriasis the patient's skin can be made clean and smooth in nine days from the commencement of the treatment by the acid, and when, as formerly, arsenic was trusted, it required at least six weeks, and even then the result was by no means so satisfactory.

In conclusion (Dr. Charteris said) there had been in the wards 252 patients during the session; and of these, excluding six who died twenty-four hours after admission, the mor-

tality was twenty-four. Many of those admitted were hopelessly ill, but it seemed inhuman to remove them to the squalid misery of the homes from which they came, and they were allowed to linger amid the comparative comfort of a well-ventilated and well-nursed hospital ward. It would be easy to show a very clean bill of health and an infinitesimal mortality if the physician was foreseeing, and fatal chronic cases unfeelingly dismissed. Such fame—if it were not a desecration of the word to call it so—could only be attained at the sacrifice of conscience and self-respect. And besides, the chronic cases would form the staple of the after-practice of the students, and the knowledge acquired of the varied phases of approaching death was an inestimable boon to them, for they could tell of this to wearied watchers, and dictate little comforts during life's last hours.

They had had an opportunity of studying nearly every disease treated of in ordinary books of medicine, and in many of these they had seen how wide was the field, how hopeful the future of practical therapeutics. Clinical experience showed how few symptoms or signs were in reality significant of any one particular disease, and how slowly but surely the art of healing would be consolidated, not by physiological experiment or laboratory dreams, but by carefully recorded facts and well authenticated recoveries when the proper remedies had been judiciously chosen. They could assist much in the work, more than they at present imagined, if when practitioners they still remained students and jotted down for publication details of cases, whether successes or failures.

THE ANATOMY AND SURGERY OF THE PERITONEUM.

By AUGUSTUS J. PEPPER, M.S., M.B., F.R.C.S.

THE serous membranes—peritoneum, pleuræ, and pericardium—are derived primarily from one common cavity, the pleuro-peritoneal. This is formed by the splitting of the ventral lamina of the middle layer of the blastoderm, the outer portion of which forms the abdomeno-thoracic wall (somato-pleure), and the inner portion the muscular and sub-mucous coats of the alimentary canal, together with certain viscera—in part or entirely—of the thorax and abdomen (splanchno-pleure). Subsequently by the formation of the diaphragm, the pleural is shut off from the abdominal cavity; a further stage consists in the separation of the two pleural sacs and the pericardium. The lower part of the alimentary canal, it will be remembered, is derived from an invagination of the epiblast from the surface, in the same way that the buccal cavity is formed above or in front. Thus at one time the alimentary canal consists of three segments, mapped off by two septa; by absorption of the latter continuity is established. The normal remains of the anterior septum we see in the pillars of the fauces, whilst the posterior vanishes, except in certain cases known as imperforate anus and congenital absence of rectum.

I now confine myself chiefly to the consideration of the peritoneum—its anatomy, pathology, and surgery. And to simplify description I propose to make four categories. 1. Developmental anatomy. 2. Acquired pathological conditions. 3. Accidents or injuries. 4. Surgical operations.

First, as to certain points consequent on developmental changes.

A. The opening of the Fallopian tubes into the peritoneal space. The ducts of Müller arise in connexion with the splanchno-pleure layer of the mesoblast, their upper or forward extremities abutting on the adjacent cavity, and later on, when these become hollow, they are continuous with the peritoneum. The practical outcome of this is the possibility of fluids injected into the uterus or infective material formed there, finding their way into the peritoneum and setting up peritonitis.

B. The splitting of the mesoblast, stopping short of the termination of the trunk behind, the peritoneum will not reach to the extremity of the mucous canals, and so we find that the lower part of the rectum and the vagina are free

¹ Paper read before the Medical Society of St. Mary's Hospital, Nov. 26th, 1879.

from the serous covering; an explanation of the feasibility of performing numerous operations on this the most important surgical region of the body—e.g., the removal of stone, the cure of fistula, the relief from retention of urine; and, last but not least, that combination of “operative audacity and surgical triumph,” the removal of a foetus from the uterus by elytrotomy in the groin.

C. A process of peritoneum accompanies the testicle in its descent from the abdominal cavity to the scrotum, and this becomes obliterated to the extent of the spermatic cord, the closure usually becoming complete at from twenty to thirty days after birth (Birkett); the lower portion, however, remains open, as the tunica vaginalis testis, which may become the seat of hydrocele, hæmatocele, &c. The usual course is for the funicular part of the vaginal process to shrink, firstly at the internal ring, then at the upper part of the testis, and finally throughout its whole length; but not uncommonly it remains partially or entirely open. Let us consider the varieties that are met with. Supposing no closure occurs, then there is a direct passage from the peritoneal cavity into the tunica vaginalis, and along this a piece of bowel or serous fluid may pass, constituting congenital hernia and hydrocele respectively. We diagnose the former in many cases by the history of the sudden development of a swelling reaching at once to the bottom of the scrotum; the latter by the reducibility of the fluid, which had before occupied the vaginal sac.

There may, however, be apparent but not-absolute obliteration of the funicular process, and so a possibility of irritating injections (though these are rarely required for the cure of hydrocele in the child) reaching the peritoneum—a mishap you may always guard against by applying pressure at the time over the external ring. Again, should the tube be obliterated only at the top of the testis, a coil of intestine comes down, and does so as rapidly as in the hernia congenita of Haller, and differs from it only in the fact of its being co-extensive with the cord. This is funicular hernia. Or the tube may remain open for a variable extent along the cord—although its continuity with the abdomen is broken, in this case a hernial protrusion must make its own sac, which latter becoming ensheathed by the funicular part of the tunica vaginalis, constitutes encysted hernia, or, as it is often ambiguously styled, infantile. Lastly, a small sacculæ may be the only deviation from the normal, and this may be the seat of encysted hydrocele of the cord.

One word about the so-called diffuse funicular hydrocele. In most text-books it is described as a serous infiltration of the cellular tissue of the cord, which I believe to be erroneous, for pressure at the internal ring would give rise to it; and were this the correct pathology we ought always to find an associated varicocele—a combination not by any means constant. It seems to me that it may be caused by two anatomical states—*a*. Fluid in the whole funicular portion of the tube, but not communicating with the cavity of the abdomen. *b*. Fluid contained in several loculi of the tube from irregular closure at several spots. It would be well to abolish the word diffuse, and to speak only of the several forms of encysted hydrocele—congenital hydrocele comprising two varieties, complete and funicular. In the female the process of peritoneum, if open, forms the canal of Nuck, and may be the seat of hydrocele or hernia.

D. There are several points with regard to the changes taking place in the peritoneum after birth due to alteration in shape and size of the abdominal viscera, to the growth of the pelvis, and to the stretching of certain parts of the mesentery and other folds. Two or three illustrations will suffice.

Enlargement of the spleen in the earlier stage is known to encroach on the thoracic cavity relatively more in the child than in the adult. This is owing to the pleuro-colic fold—which forms a kind of shelf beneath the spleen—becoming gradually stretched as life advances, by the distension of the stomach and colon, for this reason the enlarging spleen in the adult more readily oversteps its natural barrier.

Intussusception of the bowel commencing at the ileo-cæcal valve might with propriety be termed an accident incidental to infancy and childhood. There are two factors in its causation; on the one hand, an irregular peristalsis, with an empty state of the bowel; on the other, the anatomical relations of the peritoneum. In children the whole of the cæcum is freely slung by mesentery, in adults it is more tightly bound down to the iliac fossa. And bearing in mind that in intussusception of the bowel the part first invaginated

is always the most advanced, or, in other words, that the ensheathing portion becomes involuted, we see how in children this portion of the bowel easily leaves its normal situation, stretching its moorings and carrying them with it.

The bladder in children is always to some extent in contact with the abdominal wall; in adults only when distended; for in children the pelvis is but little developed. This bears upon punctured wounds of the lower part of the abdomen, and also on the operation for stone.

As an illustration of abnormal development I may cite the case of congenital defect or absence of the diaphragm.

I pass now to the second division of the subject—acquired pathological conditions. These are practically inflammation and its results. It is strange that although the three main serous membranes have their origin in common, they differ so widely in their behaviour with regard to the common causes of inflammation, each one seeming to identify itself with the viscera with which it is connected. Thus we find that pleurisy frequently follows exposure to cold; pericarditis and peritonitis rarely, if ever, as an immediate result. Pericarditis is mainly dependent on toxicæmic conditions, such as that of acute rheumatism, chronic Bright's disease, and pyæmia; whilst peritonitis is almost unknown, except as a sequence of injury, taking the word injury in its widest sense, so as to include not only direct wounds of the peritoneum from without, but in addition the irritation from physical and chemical substances that may find their way from rupture of the underlying structures, such as a hydatid cyst, gall-bladder, and abdominal viscera; as well as diseased states, spreading by continuity, such as cancer of the liver, or typhoid ulceration of the intestine. Many cases are recorded as idiopathic peritonitis simply because a more rigorous search has not been instituted. How easily a minute perforation, or a body of small size (in one case the operculum of a whelk) impacted in the vermiform appendix, may be overlooked in presence of the more staring pathological appearances. It is only recently that I demonstrated in the post-mortem room a hole little larger than the diameter of a pin in the ileum of a patient who had died from perforative peritonitis complicating typhoid fever. This probably would never have been seen had we not carefully flushed the intestine with water, and yet, small as it was, no one could entertain the least doubt as to its having been formed during life—a small, deeply-excavated ulcer on the one side, an excessive amount of lymph on the other, and the aperture itself bounded by a narrow ring of necrosed tissue.

The symptoms and pathological appearances of peritonitis vary greatly in different cases, according to the intensity of the cause, the rapidity of the process, and the general condition of the patient. Thus it may be chronic, partial, and adhesive, as when it occurs in the course of cancer and tubercular enteritis without perforation. It may be latent, as we find after the operation for strangulated hernia in old people, or where the bowel has been acutely nipped for a long time. This, instead of being looked upon as a special kind of peritonitis, should be considered simply as peritonitis in a subject with depressed vital powers. The pathological changes are going on, but the general response is feeble. Finally, we meet with cases in which the inflammation is so rapid that it assumes a purulent form from the first.

I would call attention to two of the more important symptoms of the disease. Firstly, the *Pulse*. In the sthenic form it is said to be rapid, small, and wiry; this is due to reflex contraction of the arteries generally, excited by the irritation of a large number of nerves, together with a powerfully-acting heart. In the asthenic, and in all cases in the later stages, it is rapid, small, and compressible, a paralytic condition taking the place of, or succeeding, the irritative. Secondly, *Tympanites*. This is caused by increased pressure from accumulated gases from within, and paralysis caused by inflammation of the muscular coat from without. It is curious to what extent cellulitis may spread without producing peritonitis. In a case of lithotomy performed at this hospital purulent exudation had extended from the pelvis along the course of the ureter and iliac vessels, and yet there was no peritonitis.

One result of chronic thickening of the membrane is to diminish the liability to acute general inflammation, so that the sac of an old hernia may be opened with much less risk than that of a recent one. This is an instance of the general pathological law—that slowly progressing lesions produce less marked effects than others of even less extent with

rapid onset; for the parts involved appear to accommodate themselves to their altered mode of life. Thus a tumour within the skull for a long time may give but little evidence of its existence; whereas a hæmorrhage as large as a bean may be followed directly by complete hemiplegia. Again, the prognosis in secondary amputations for chronic disease is more favourable than primary ones for accident. We gather from this the indication that major operations of expediency should not be performed on patients immediately taken from active life, but they should be confined to bed for some days prior to surgical interference.

This brings me to the third part of my subject. The peritoneum may be bruised, extravasation occurring in the retro-peritoneal tissue; this in a healthy subject almost invariably leads to absorption, but if the continuity of the serous surface be broken, and especially if the lesion communicate with the air, the danger is manifoldly increased. The treatment of a simple, incised wound consists in passing the ligatures through the entire thickness of the abdominal wall, so as to bring the divided edges of the peritoneum together, in order that the inflammatory lymph may seal the wound from within. It has been objected that the needle-punctures may of themselves set up peritonitis; but surely this possible drawback is more than counterbalanced by the advantage gained. A slight amount of local peritonitis is advantageous in order to prevent discharge from the wound if it occurs from finding its way into the peritoneum. In lacerated wounds where adhesion by the first intention is impossible, it is best to leave them freely open to admit of the escape of pus and débris externally, there being less danger than would at first sight appear of noxious matter making its way into the abdomen; remember that in the natural condition there is no such thing as a peritoneal cavity; it is only a potential space, and the atmospheric pressure on the abdominal wall tends to prevent the separation of the parietal and visceral layers. Penetrating or perforating wounds, such as a bayonet-thrust, on account of the small intestine being loosely slung by the mesentery, may happen without injury to the coils of gut, these being pushed aside by the advancing body.

There are certain portions of the viscera less liable than others on rupture to extravasate their contents into the peritoneum. The best example is the duodenum in its second and third parts; for although this portion of the bowel, on account of its anatomical relation to the spine, is exposed to greater chances of injury from blows, still as its posterior surface is free from serous membrane, peritonitis from its rupture is less likely to occur than from rupture of other parts of the gut. The same argument applies, though with less force, to the cæcum and ascending and descending colon.

Large vessels may be severed and a loss of blood sufficient to cause death may occur without there being dulness on percussion, the extravasation being found diffused widely in the sub-peritoneal tissue; and yet as a matter of routine we percuss the flanks in severe abdominal injury, knowing that if the blood be poured into the cavity of the peritoneum to a fatal extent, it will mainly find its way into the more dependent parts.

Surgical operations about the abdomen are planned where possible so as to avoid implicating the peritoneum, it being found that under these circumstances the risk is much diminished. This it is which gives lumbar colotomy the superiority over Littre's operation, in spite of minor drawbacks.

Since the introduction of a rational system of antiseptics surgeons have become less timorous and unsparing with the use of the knife. I emphasise the word "rational," because antiseptics are not infallible. They cannot prevent contagion being carried by the unwashed hands of obliging assistants, or by a forceps, on which, perhaps, cling products of decomposition of blood, &c., from a former operation. There are certain operations which must be done through the peritoneum, such as gastrotomy, for establishing a fistulous opening into the stomach; gastrotomy for relief in certain cases of acute obstruction of the bowels, and for Cæsarean section. There are more which are done behind it—e.g., the perineal, rectal, and supra-pubic operations for stone; rectal and supra-pubic puncture for retention of urine; ligature of the main arteries of the abdomen; the removal of a calculus from the pelvis of the kidney, and the removal of a foetus from the uterus in cases of extreme pelvic deformity in lieu of the older and probably more dangerous procedure. Finally, there are the so-called tappings through the peritoneum, for ascites, for ovarian cyst, for hydatids,

for excessive tympanites, and for accumulation of fluid in Douglas's pouch, the last operation performed through the vaginal wall.

One word of advice and I have done. Never pass a trocar into the abdomen without having previously introduced a catheter into the bladder, and without having made yourself sure, by percussion, that no part of the bowel lies in your path by reason of an elongated mesentery.

ON IRREGULAR GOUT, WITH REMARKS ON THE PATHOLOGY OF GOUT.

By W. R. THOMAS, M.D., M.R.C.P.,

PHYSICIAN TO THE SHEFFIELD PUBLIC HOSPITAL; LECTURER ON MEDICINE, SHEFFIELD MEDICAL SCHOOL.

GOUT presents itself in so many different forms that it is often difficult to recognise it when we meet with it, and many cases of real gout are no doubt frequently overlooked because the disease has not been found in its accustomed seat.

One patient suffers from bronchitis, another from psoriasis; one may have gravel with or without albuminuria, another may have gout in his big toe. It may present itself as asthma, or again as neuralgia of the face. One may be alarmed by his having to be treated for apparent gonorrhœa, while another may have diarrhœa with piles and tenesmus—all of which diseases may be but local exhibitions of constitutional diathesis.

Frequently I have found that some of the skin diseases we meet with are entirely dependent upon the gouty diathesis. One patient had been suffering from psoriasis for three or four years, had had the usual remedies prescribed, but without success. Finding that his brother had suffered from gout, that his father had died of apoplexy, and had often been laid up with gravel, I treated the case as one of gout, and the patient gradually improved. I really looked upon this case as essentially gout of the skin, considered that the gravel the father suffered from was dependent upon the same cause, and that in all probability the apoplectic attack was owing to chalky deposit in the walls of the arteries of the brain, in consequence of which these walls were impaired, ultimately gave way, and apoplexy was the result.

I have treated several cases of eczema in the same way whenever I have been able to find that there was any tendency to gout.

A patient of mine, who had suffered for several years from severe attacks of this complaint confined to the big toe, who had been a heavy drinker, and had lived well, one night, when the pain in his toe was excruciating, was tempted to put his foot in a vessel containing cold water to relieve the pain. This did certainly relieve his pain, but soon afterwards his breathing became extremely difficult. I had to be sent for, and found that he had all the ordinary symptoms of asthma. Having been told of the manner in which he had treated himself, I naturally looked upon the asthma as dependent upon gout, and applied local remedies to try, if possible, to cause a return of the disease to the toe, but without avail. This gentleman continued to have severe attacks for two years, but he found that when he abstained from excessive eating and drinking, and took a reasonable amount of exercise, the pain to a certain extent was relieved. One day, when jumping out of a cab, he fell, and was laid up for weeks, for his old friend had returned to his big toe, took up its residence there, and frequently gave tokens of its presence whenever the owner of the toe acted unwisely.

How often we meet with patients who have suffered for days from many of the premonitory symptoms of gout, who have been, as it were, relieved of the gout by the passage of large quantities of gravel, in many instances calculi, and in one of my own cases the appearance of gravel alternated with gout in the big toe: a hint that we should treat such symptoms as gout whenever we have any suspicion of gouty diathesis, or where the habits of the patient tend to make us think that it might have been acquired.

One of my patients used to suffer from excruciating pain in the right sciatic nerve, along the greater part of its course; the attack generally lasted three or four days, and after an absence of four or five days returned. In this way he dragged on a miserable existence for three months. Finding that his grandfather had been a gouty patient and that one of his sisters had recently suffered from the same complaint, I treated this case as such with a certain amount of success. The following year he continued to pass for a considerable period large quantities of gravel, suffered from severe pain in the back, but never again from the sciatica; in fact, he became a very temperate man in every way; and I believe by so doing he succeeded in warding off the attack. I regard many of the neuralgiæ as really dependent upon the gouty diathesis probably due to the presence of chalky deposit either in the sheath of the nerve or somewhere in its course, in either case producing pain and irritation.

Frequently the gouty patient complains of pain in the back, and when the urine is examined, in addition to the salts, it contains albumen, a sign that disease of the kidneys is being produced by the gouty diathesis, and that there is danger of their being less and less able to perform their functions daily, more especially when deposit takes place in them, as proved after death by the appearance of white streaks of urate of soda.

I look upon gout when not hereditary as a disease invariably produced by excessive indulgence in food or drink, oftentimes accompanied by want of exercise. Excess of food by supplying excess of nitrogenous materials for the blood, tends ultimately to produce excess of urea and uric acid, which have to be expelled by the kidneys. These organs perform their functions properly for a while, but the excessive work thrown upon them for a considerable time ultimately tends, as in chronic alcoholism and disease which interfere with the action of the skin, to produce disease and consequent inefficient action of the kidneys.

Distilled spirits do not seem to produce gout to the same extent as wine, porter, and ale. Although there is a great hereditary tendency in gout, still generations do escape because the children, having seen the sufferings of their parents, sometimes have the good sense to avoid the exciting causes, and thus escape.

We know that in gout we find an excessive quantity of uric acid in the blood, and that the quantity daily excreted by the kidneys is diminished, and as we frequently find that in other diseases accompanied by excessive formation of urea and uric acid the kidneys are quite able to excrete as much as is required of them, we may safely come to the conclusion that from some cause there is deficient action of these organs, and consequent retention of materials which ought to have been excreted; for the urates, cartilage cells, fibrous tissue, and epithelial cells seem to have an affinity, and deposit in and around them takes place, producing diseases of joints, eruptions of skin, and inflammations of mucous membranes.

New deposit may take place in the kidneys, interfering still more with the functions of those organs, to such an extent that it is not satisfied now with small joints at a distance from the heart, but attacks the larger joints.

Many can indulge in eating and drinking for years, and yet never suffer from gout. In such patients there does not seem to be any hereditary tendency, or they have organs which perform their functions well, and thus the blood is not, as it were, rendered impure.

Every excreting organ in the body has certain functions to perform, and if these are not performed properly either some other organ has to do the work, or there is retention of matter for excretion in the blood, unless it be deposited somewhere, in which case it is practically excreted; in fact, every portion of the body may be said, by relieving the system of what that part requires for its nutrition, to act as an excreting organ. Even the bones by taking up certain earths act as excreting organs to a certain extent.

Now, when there is excess of hydro-carbonaceous matter in the blood, we find that there is a tendency to increase of fat all over the body. These cells, which naturally tend to take up fat, now that it is in excess, take it up in excess, showing that the presence of certain materials in the blood influences the formation of tissue.

When the kidneys act imperfectly, and there is consequent retention of certain materials in the blood, these are taken up by cartilage, fibrous tissue, and epithelial cells, and produce gout.

Sheffield.

NEUBER'S BONE DRAINAGE-TUBES.

By GEO. GRANVILLE BANTOCK, M.D., F.R.C.S. ED.,
SURGEON, SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.

In the paper which led to the discussion on antiseptics at St. Thomas's Hospital in December last, Mr. MacCormac first in this country drew attention to the use of Neuber's decalcified bone drainage-tubes. At that time I was about to remove a breast, and after carefully going through Neuber's paper I determined to try his tube. Accordingly I procured from Krohne a set of tubes prepared as the author directs, and in using them strictly followed his practice. That case was published in THE LANCET along with another of excision of the sac of a femoral hernia. Since then I have used the tube in a second extirpation of the breast, and the result has been uniform in all these cases. The first two tubes were made from ox bone, and the third from ivory.

Dr. Newman of Stamford has recently briefly referred to two cases in which he had used these drains. His object was to express his disappointment, for he said the tubes became flattened, collapsed, and blocked, and serum accumulated. He omitted to say what ultimately became of them. I have heard of another case—excision of the mamma—done under strict Listerism, in which, owing to the occurrence of erysipelatos inflammation, the tube broke down, and the pieces could only be got away with considerable difficulty. With such experience I am in a better position to give an opinion on this subject.

Neuber tells us that the bone drain inserted in a fresh wound remains for twenty-four hours without any material change. Then its surface loses its smoothness, and the walls gradually become thinner. On the fourth or fifth day the walls are partially perforated, and so thin that they can no longer resist the pressure of the surrounding tissues, and the tube gets flattened. Absorption then goes on more quickly, and after the sixth day only a gelatinous body remains, of which no trace can be found on the tenth day. The quickness with which a tube is absorbed is not in all cases alike. It depends on the individual energy of the local action; placed in a gangrenous wound it is hardly absorbed at all, whereas in a healthy granulating wound that process is very rapid.

As I have already said, the results in the cases in which I have used this drain have been uniform, so that the description of one may serve for all. The tube was blocked on the second day, and as far as I could make out the blood-clot within was already undergoing organisation. Moreover, the tube was fixed, and would not yield in the slightest degree to a moderate pull. On the fourth day the projecting part of the tube had dried up, and was cut off. After this the skin soon closed over the end. But the enclosed part of the tube could still be felt of its original length, and flattened. This was the state of things in the first patient when she left the hospital at the end of twenty-seven days (her stay was protracted by an attack of menorrhagia arising from the existence of a fibroid tumour of the uterus); and the adhesion to the skin was so strong that the tube could be freely moved about with it. A month after the operation, in the second case, the tube had undergone no diminution, and in the third case—a breast case—there was no perceptible change when she was examined after the lapse of two months, and the ends of the tube could still be seen projecting under the skin. In all these cases union was absolutely by first intention, without the slightest blush throughout the length of the wound. The first and second operations were done under the spray, but in neither of them was the raw surface washed with the 1 in 20 solution. In the third case the operation was done without the spray. But as a solution of phenol (1 in 60) was used for the sponges and instruments, care was taken to prevent the access of more of the antiseptic than was unavoidable. Of the two breast cases the latter was the more satisfactory in the matter of discharge, the thymol gauze, after the first dressing, presenting a mere stain not larger than a penny piece.

Now, how is this difference in the results reported by Neuber and myself to be accounted for? Neuber says the tube is absorbed. I cannot but think that in this he is in error, and that he has mistaken for absorption the gradual solution of the material during continued discharge.

In one breast operation I had to scoop out a lot of enlarged glands from the axilla, and I employed two skeins of catgut for the drainage. As the healing went on, although the skin presented its natural appearance, there was a considerable serous discharge, and the separate strands of the catgut evidently underwent a process of solution. This free serous discharge is characteristic of Listerian treatment, and I attribute its occurrence in this last case to the action of the strong carbolic acid (5 per cent.) solution with which I washed the cut surfaces. Here then, it appears to me, we have a satisfactory explanation of the point of variance between Neuber and myself. In my practice the discharge is trifling, after the immediate oozing has ceased, and the tube remains incorporated in the wound. With Neuber it is melted down and washed away. The strong solution is used, the cut surfaces acted upon are cauterised and have a whitened or greyish appearance. That is to say, they are covered with a film of coagulated albumen, which is nothing more than dead matter, and, impregnated as it is with a powerful irritant, must come away in great measure in the form of discharge. This is the peculiarity of Listerian wounds, and hence the necessity of Listerian drainage. It may be true that without the drainage the germs are destroyed, but the mischief done mechanically by tension from pent-up fluid would be as disastrous as anything occasioned by living organisms.

Why this inconsistent cauterisation should be put forward as essential to perfect Listerian practice I have always been at a loss to understand, seeing that a solution of half the strength is considered sufficient to cleanse the instruments, and for the spray. Surely, if the germs on the hands, instruments, and sponges succumb to a solution of 2½ per cent., it cannot be necessary to kill a part of the raw surface with a 5 per cent. solution to involve the few germs that may be there in the catastrophe. It is not maintained that the external germs—the spongel, instrumental, manual, imported, vagabond germs—are in any way different from the germs in the wound, the colonised germs; so that if 2½ per cent. is enough for the one, 5 per cent. must be too much for the other; or if 5 per cent. be the true germicidal proportion, the germs in the 2½ per cent. spray may still dance and be merry as notes in the sunbeam. Five per cent. either is or is not necessary: if necessary, the spray is a mockery; if not necessary, the wound treatment is bad surgery. It looks as if there were no escape from the horns of this dilemma.

The conclusions, then, that I have to draw with regard to the bone drainage-tubes are—1st, that they may be used without any immediate mischief in cases where they are wanted only for a short time; that is, in cases where there is a discharge only for the first few hours after operation. But in my experience there is even then this disadvantage, that with rapid union they remain encased and unabsorbed too long, and in that condition they generally cannot be said to do any good, and they may do harm. Time will show this. 2. When, however, from the nature of the case or the germophobic strength of the dressings the discharge is expected to be copious, and to continue for several days, the bone tubes are wholly inapplicable; hence it need excite no surprise that in Neuber's ovariectomies their use was "disastrous." For the drainage after this operation the glass tube must hold its own against all comers.

Granville-place, Portman-square.

TWO CASES OF MYXŒDEMA.

BY THOMAS INGLIS, F.R.C.P. ED.

So few cases of myxœdema have been recorded in the medical journals that it is clinically important to note a short account of them as they occur, as this form of disease is somewhat uncommon, is insidious in its symptoms, and its treatment hitherto difficult and unsatisfactory. The morbid condition was first pointed out by Sir William Gull in an article on "A Cretinoid State supervening in Adult Women,"¹ and was subsequently more fully described, and its pathology partly elucidated by Dr. Ord to the Medical and Chirurgical Society of London;² while cases have been observed by Drs. Duckworth, Sanders, and Savage.³ Its

most prominent feature consists of a jelly-like formation in the subcutaneous areolar tissue, which gives the patients a stolid, puffy appearance, approaching that of the cretin. Their appearance is suggestive of the dropsy of recent renal disease and the passive anasarca in cardiac complaints, but we find the urine usually normal till the termination of the illness, and the heart is also healthy. All the patients hitherto observed have been females, except a doubtful male case under the care of Dr. Savage. I will give a general outline of two cases at present under observation.

T. W—, a plumber, of temperate habits and good general health, became depressed in mind owing to his wife's bad conduct, and was admitted to an Asylum, labouring under melancholia, with strong suicidal tendencies, when the following particulars were ascertained. There was no hereditary predisposition to insanity or other neurosis, and he had two healthy children. He had taken a large dose of laudanum with suicidal intent, and required the application of remedies and artificial respiration when admitted. He answered questions in a confused way; stated he wished to take away his life.

In three months he made a recovery from the melancholia, but was observed to be slightly enfeebled in mind.

When the first symptoms made their appearance, a general swelling, affecting principally at first the eyelids and hands, and afterwards extending over the extremities and body, gradually and insensibly came on. This swelling was first noticeable about the face, where the skin of the eyelids became puffy, wrinkled, and waxlike, widening the nose, and causing a general blurring or obliteration of the facial expression, and giving it a flattened, cretinoid aspect. The nose looked levelled down, the lips were thick and heavy, the lower one protruding. The tongue looked too large for the mouth, but was not oedematous, while the interference with the function of speech was very evident, articulation being slow, indistinct, and paretic. The mode of speech resembles that of the hemiplegic, and the thickened articulation of the epileptic, and was most affected in the morning. The hands got much enlarged and "spade-like," and he complained of their being stiff, cold, and numb. On pressure over the front of the tibiae, where the oedema was considerable, there was no pitting. The urine contained no albumen; sp. gr. 1015. The heart's action was slow and laboured, but the sounds were healthy. The surface of the body was always cold to the touch. Temperature in axilla, 95°. He never felt warm even in the hottest weather. All over the skin is dry and brawny, and its sensibility is slightly impaired, somewhat resembling scleroderma. Although the skin is dry it is often subject to short-lived perspirations. There are no reflex contractions on tickling the soles of the feet. There is no atrophy of the muscles, but the grasp of the hands is feeble, chiefly from inability to flex them. There is an absence of excitability of the muscles of the legs and arms. On faradising the muscles of his face only a slight response (Weiss, fifty cells) was obtained in them. On applying the electrode of the intermitted battery current to his scalp, where there is little oedema, there is strong reaction, and he then says he sees flashes before his eyes.

The fact that the faradaic contraction of the muscles where the oedema was marked is much impaired would point to a degeneration of the nerve-tissue at the periphery, as it is known that the normal excitability of the muscles is retained after gross lesions of the central ganglia, as in hæmorrhage or softenings; while, after an injury to a nerve, such as the sciatic, there is no electrical response. On the other hand, that there is no atrophy of the muscles militates against the theory of peripheral nervous degeneration, and it is probable that the myxœdema presents a mechanical obstruction to the stimulation of the nerve endings. The helplessness and slow mobility appear to be due more to the mechanical obstruction of this mucoid degeneration than to defective innervation. He presents a blown-up, water-logged appearance, and waddles like a duck when walking. The appetite is usually very bad, and he can go without food for days and not feel hungry. When he does eat, the food tastes badly to him. Bowels are constipated. He has become rather deaf, while sight and smell remain good. He has become very lethargic, and sleeps a great deal. The mental characteristics are now slight enfeeblement; memory slightly impaired as to recent events. In the mind, as with the body, the period of activity is over, and his small routine duties are performed in an automatic, listless manner.

¹ Clin. Soc. Trans., vol. vii.

² THE LANCET, Oct. 18th, 1879.

³ Journal of Mental Science, Jan. 1880.

The second case is that of a woman, aged thirty-nine, of good general health, the mother of eight healthy children. She comes of neurotic stock, with an hereditary predisposition to insanity and other neuroses. Her mother died of apoplexy, and a sister was treated in an asylum for puerperal mania. Her illness came on five years ago, at the same time as an attack of melancholia, and was attended with perversions of the special senses. She said everything smelt of gunpowder. She presents the same bodily symptoms as T. W—, but in a lesser degree. Her mental condition is now permanently impaired. Three years ago an attack of mania followed the melancholia, and she had to be sent to an asylum. There she expressed many changing delusions, as that she was a queen, and sent to Edinburgh Castle for an escort to take her to Leith Fort. Sight is good, but the senses of smell and taste are impaired. She alleges that she smells snuff in her food, and that it tastes like poison. Numerous warty growths are scattered over her arms. Like the man she feels worst in the morning, when, she says, she can hardly see. The urine is natural, sp. gr. 1010. The heart's action is regular, the second sound being sharp and accentuated.

Her natural temperament was amiable, but she is now irritable, passionate, and sometimes violent without cause. Is becoming demented, is silly and childish in conversation, and frequently talks incoherently to herself. There is loss of that important faculty, the attention, and the judgment is warped, but the memory is still tolerable, and her affection for her children remains.

That the central nervous system is largely involved in myxœdema seems unquestionable, as in all the cases on record mental disturbance in some degree has been observed, ranging from perversion of the affection, irritability, slight depression, and loss of enjoyment in life, to aggressive mania and fatuity.

It appears to be a general progressive disease, which distinguishes it from simple scleroderma.

Post-mortem examination by Dr. Ord revealed a general œdema of the subcutaneous areolar tissue, which was composed largely of mucin and not of serum. It was also found in the internal viscera. The arteries of the brain were much degenerated and atheromatous, but the microscopic cerebral structure does not appear to have been fully examined. Where the extremities of the cutaneous nerves were observed, it was seen that they were enveloped in a soft transparent substance, so as to be padded and removed from the ready operation of incident impulses, tactile, thermal, or chemical.

When fluid accumulates in the subcutaneous areolar tissue we have a tense shining skin, pitting on pressure, and making its appearance in the lower extremities. When from impoverishment of the blood or pressure on veins we have dropsy, the œdema at first is not stationary, but is altered by position. In myxœdema we have the reverse. Scleroderma differs from it in being a sclerosis of the areolar tissues, and not an elastic mucoid change, but a limited indurated change unaltered by compression.

Although mental disturbance or aberration in some phase exists in all cases, the disease does not necessarily lead to insanity when it supervenes. This is possibly due more to the individual temperament or constitution of the patient than to the *materies morbi*, and in this particular it resembles many lesions and injuries of the brain, which frequently but not inevitably cause mental disorder. Its characters are so varying that it does not follow any typical course, but generally the lethargy and heaviness of the body find a reflex in the inactive and torpid mind. While the delusions and perversions of the special senses in the case of Mrs. H— are undoubtedly attributable to disordered brain function, the occasional profuse perspirations are also the indication of a failure of nerve power, and, like phthirical sweating, are due to the defective innervation of the nerves controlling the sweat-glands.

The irritability and mental excitement noticed in the first stages are probably the resultant of the action of poison on the cerebral convolutions, as when poisons act on the intelligence, such as alcohol or opium. There is first a high stimulation and sur-excitation, and ultimately derangement of the intellectual functions.

In some cases the departure from the normal mental state at the onset of the disease is marked more by a change in tone than by an actual state of insanity. The man feels ill, loses his sense of well-being, spontaneity; he feels uncomfortable, irritable, and listless—a phase of mild melan-

cholia. The changes come on slowly and insidiously; the alteration is noted first in temperament and disposition.

Dr. Ord is uncertain whether this mucoid change is a new product, the result of a disordered nutrition, a degeneration altering the function of the supreme cerebral centres, or a retrograde metamorphosis to a lower type, such as cretinism. Certainly the mental and bodily symptoms show a marked filiation to this disease.

I look upon myxœdema as primarily a nervous disease, and that the grosser changes in the skin and viscera are caused by deficient absorptive action of the lymphatics, the result of trophic changes in the cells of the higher ganglia.

The treatment of the disease has hitherto been very unsatisfactory, and the administration of nerve tonics, galvanism, and baths appear to have no beneficial effect, either in favouring the absorption of the deposit, or checking the progress of the disease, and at the best exercise only a palliative influence.

Deeping St. James.

ANTISEPTIC MIDWIFERY.

By WALTER VERDON, F.R.C.S.

THE following case is, I think, of interest in showing the value of Mr. Lister's treatment applied to midwifery.

Lately I have used antiseptics in ordinary midwifery cases, and with marked benefit. The discharge ceases sooner and does not become offensive. In some cases this disappears entirely during the first week. It is necessary, however, in order to obtain a good result, to guard against the admission of septic air both during and after confinement—to view the uterine and vaginal lesions in the same light you would the wound made in a subcutaneous operation, and as carefully protect them from septic influence.

In the case I quote below, the patient was exposed to the poison of erysipelas both during and after labour; and though she had a slight attack of cutaneous inflammation accompanied with fever, the uterine wound remained intact; the poison having no more influence upon it than it would have upon a wound caused by subcutaneous rupture of a muscle.

Mrs. T—, weak and anæmic, at full time, had suffered from frequent pains for two days. She had not sent for assistance because she did not think the labour far enough advanced, but now felt so exhausted she wished for help. The os was now fully dilated, membranes ruptured, head above the brim, pelvis roomy, pains frequent and short; the head descended with and receded after each, making no progress; pulse 98, weak and compressible; the patient was much exhausted. I then determined to use the forceps, and also to take every antiseptic precaution.

I syringed out the vagina with warm carbolised water; also had a small basin of carbolised oil at hand for the instruments, hands, &c., and to anoint the labia and adjacent parts. All vaginal manipulation was performed beneath the spray, and with very little traction the child was born. The after-applications were diapers soaked in carbolised oil and carbolised tow, and an injection of carbol lotion three times daily.

On the second day after confinement I found the nurse was suffering from an acute attack of erysipelas of the face; she told me she was feeling ill and her head felt tender the day before the confinement. She had slept with the patient on the night of the labour and on the following night.

On the third day the patient complained of sore-throat. Pulse 120; temperature 102° F. Vaginal discharge free from putrefactive smell; urine clear and copious.

On the fourth and fifth days the patient felt very ill and complained of pain in the right leg. Her tongue was coated; pulse 120. Still the vaginal discharge was going on satisfactorily, but there was a patch of cutaneous inflammation on the right thigh from the buttock extending almost to the knee.

On the sixth day the discharge ceased and did not return. The pulse remained above 100 until the eleventh day; the redness disappeared on the eighth day.

The child also was the subject of an unhealthy ulceration round the umbilicus, preceded by a superficial inflammation extending to the groin.

Both the child and mother made a good recovery.

Brixton-road.

A Mirror

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

MIDDLESEX HOSPITAL.

TUBERCULAR PERITONITIS IN AN ADULT; NECROPSY; REMARKS.

(Under the care of Dr. FINLAY.)

MARGARET F—, aged thirty-four, married, was admitted on Oct. 1st, 1879. She had been an inmate of the hospital for a fortnight in June, under treatment for pleurisy, but with this exception she had enjoyed fair previous health. She was one of a family of twelve, all of whom, with the exception of herself, had died young—one at the age of nine months of "water on the brain," and another of consumption at the age of seventeen. Her own family consisted of five, all apparently healthy. Twelve days before admission her abdomen began to enlarge and to be painful and tender, especially over the hypogastric region. She had been troubled by cough since leaving the hospital in June, and she had lately lost much flesh.

On admission she was emaciated, and had a pale, earthy face and anxious expression. She complained of enlargement of the abdomen, and pain which was referred chiefly to the iliac and hypogastric regions. She was troubled also with frequent cough, accompanied by froth and mucopurulent expectoration, as well as with frequent and profuse menstruation. The temperature was 102° 6', pulse 108, and respiration 27. Her abdomen was uniformly enlarged, measuring at the level of the umbilicus thirty-five inches in circumference, and was everywhere tender on pressure. There was dullness in the flanks, shifting with change of position; and the superficial veins were prominent, but there was no ascitic wave. The areas of the liver and the splenic dullness appeared normal. In the chest, the percussion and auscultation signs were fair over the right side, but resonance was impaired over the upper half of the left lung posteriorly, and the breathing at this spot, as well as in front, was bronchial in character, and the expiration was prolonged. About the middle of the left back the breath-sounds were tubular, and were accompanied by crepitation. The heart-sounds were normal. The urine had a specific gravity of 1020, and was free from albumen. Uterine examination failed to detect any cause for the menorrhagia.

On Oct. 11th it was noted that the abdomen was more tense and shiny, measuring thirty-six inches at the level of the umbilicus. A week later the cough was more troublesome, and crepitation was more distinct over the left back, extending to the base, while moist sounds of very fine quality were heard also at the right base posteriorly. There was also a sense of fluctuation felt across the abdomen.

During her stay in the hospital she had frequent attacks of vomiting and diarrhoea, the stools being watery and dark in colour; the abdominal pain and tenderness persisted, and the woman was often delirious in the night. Her evening temperature ranged from 99° 2' to 102° 4', and she gradually sank and died on the twenty-first day after admission.

The following is a note of the post-mortem examination made by Dr. Coupland twenty-one hours after death. Abdomen distended; numerous linear atrophicae in skin of abdomen. On opening the abdominal cavity, the liver, considerably enlarged, was found adherent to parietal peritoneum, and the intestines, matted together, were also adherent, but the adhesions could be separated. The peritoneal cavity contained four pints of blood-stained fluid, most of it lodged in the lower third of the cavity, but some also was contained in loculi between and around the intestines. On carefully detaching the coils of intestine from one another, their serous coats were found to be everywhere thickly covered with granulations. In addition, there were numerous and extensive patches of extravasated blood on the intestines, as well as beneath the parietal peritoneum. The stomach was large, its mucous

membrane thick and soft; the walls of the lower end of the oesophagus for two inches presented a blackened and softened appearance (from post-mortem digestion). The mucous membrane of the intestines was generally pale, but was nowhere ulcerated. The liver was large, but not increased in weight; portions of it floated in water; it was pale, of a yellowish colour, of greasy appearance, and extremely friable in all parts. The spleen was pale and soft; and the kidneys were tough and engorged, with some adherence of capsules. The heart contained soft gelatinous clot in the right cavities, and the mitral valve was slightly thickened; it weighed only 7½ oz. The right lung was adherent, pigmented, slightly emphysematous, and congested posteriorly. The left lung was very firmly adherent, occasioning much difficulty in removal. The upper fourth of the lower lobe was consolidated, presenting on section a dark greyish-black appearance. In the midst of the altered tissue were some small, irregularly-shaped vomices, which were full of puriform secretion. The right lung weighed 17 oz. and the left 20½ oz.

Remarks by Dr. FINLAY.—It seems proper to call the foregoing a case of tubercular peritonitis, because although doubtless secondary to destructive disease of the lung, the abdominal symptoms were those chiefly complained of, and the brunt of the disease was borne by the peritoneum. Tubercular peritonitis in the adult is by no means a common disease. By this it is not meant that a certain amount of tubercle of the peritoneum is not found frequently in bodies that have succumbed to phthisis; but in such cases there is commonly found more or less tubercular ulceration of some part of the intestines, and the peritoneal tuberculosis is seen to be secondary to the lung disease not only in point of time, but also in respect of symptoms and importance. In the latter respect, at least, the case above recorded presents a different aspect. The case was further interesting from its extreme clearness as regards diagnosis. The personal history of the patient, no less than her family history, together with the physical signs detected in the lungs, rendered this a matter of great ease and certainty.

SHEFFIELD GENERAL INFIRMARY.

COMPOUND COMMINUTED FRACTURE OF THIGH; RECOVERY.

(Under the care of Mr. JONATHAN BARBER.)

FOR the following notes we are indebted to Mr. Charles M. Goyder, late house-surgeon.

J. H—, aged forty, a forger, was admitted December 6th, at midnight, suffering from injury to thigh.

Whilst intoxicated the patient attempted to cross the street, and was knocked down by a tramcar, the wheels of which passed over his left thigh. He was pale, and collapsed; his face disfigured and contused; the pulse small and regular; skin cold and sweating. The left thigh was much mutilated. In the upper third there existed a perforation the size of a penny piece, and in the lower third a large rectangular skin-flap was separated from the subjacent muscles, and the thigh-bone was fractured at the junction of the upper and middle third, obliquely from behind downward to forwards. The finger placed in the wound detected a number of comminuted fragments. The upper circular wound seemed to have been produced by the protrusion of the upper fragment through the soft parts. In addition to these injuries, the femoral artery was completely detached, pulsated, and was apparently enclosed in its sheath. The limb below was cold, but sensation was present, and the tibial arteries pulsated.

Mr. Barber saw the patient shortly after admission, and decided to allow reaction to set in before doing anything.

On Dec. 7th the patient's condition was better; the pulse was quick, and there was not much pain. The foot was warm and the sensation good. In consultation it was determined to treat the case antiseptically, amputation so high up being considered as well nigh hopeless. Accordingly the wounds were syringed with a 5 per cent. solution of carbolic acid, and the limb was dressed under antiseptic spray. Two drainage-tubes were inserted, the contused flap before noticed was stitched up, and an outside long splint was applied. Evening temperature 102° F.

Next day the wound was dressed and looked well. Pulse 120, tongue dry. Temperature 103° F. On the 10th the wound was dressed again; the skin-flap was sloughing, but otherwise the wound looked healthy. A bruise of violet tint

surrounding the thickness of the thigh, indicated the place at which the wheel passed over the limb. General condition good; temperature 102° F. On the 15th he was doing well; there was a plentiful discharge, which was becoming purulent, but was quite sweet. On the 16th the femoral artery was felt beating strongly in the wound; and on the 20th there was considerable bleeding from a branch of femoral artery, which was exposed and ligatured. The general condition was good. On the 27th the limb, which had been dressed daily, was placed on Dr. Heath's (of Newcastle-on-Tyne) splint.

On Jan. 11th, 1880, the patient expressed himself as being much more comfortable in the new splint. The wound was healing slowly, and the pulsation in femoral artery was less. The general condition was much improved.

From this time the wounds gradually closed, and the discharge diminished; the patient's general condition became daily more comfortable, the appetite was good, and the pulse regular and good.

From Feb. 2nd the limb was dressed at intervals of three days.

On May 13th two necrosed fragments of bone came away, and the splint was taken off, and the limb was laid between sandbags.

On June 25th there was good union, with three-quarters of an inch shortening. The wounds had contracted into sinuses, and the femoral artery appeared to be thrombosed at the seat of injury. The general health of the patient was extremely satisfactory.

TYRONE COUNTY INFIRMARY.

CASE OF STRANGULATED FEMORAL HERNIA; OPERATION WITHOUT OPENING THE SAC; RAPID RECOVERY.

(Under the care of Dr. EDWARD THOMPSON.)

JAMES F—, aged fifty-five, a delicate, decrepit-looking old man was admitted on May 15th, 1880, suffering from great sickness, with violent pain in the lower part of the abdomen. The day previous to his admission he was making some unusual exertion when he experienced a sudden pain in the abdomen as if something had given way, and was almost immediately seized with sickness and a feeling of faintness. He sought advice at the dispensary of the district, and was there recommended to the hospital.

On admission the face was pale and anxious, the pulse fluttering and very feeble, and the extremities were cold. There was constant vomiting, together with pain on pressure, over the lower part of the abdomen. The bowels had not moved since the previous day. Temperature 99°; urine diminished in quantity. In the usual situation a very small femoral hernia was readily detected. Taxis having proved ineffectual, it was determined to delay operative interference no longer.

The patient was accordingly put under the influence of ether, and the operation was done with the usual antiseptic precautions. The skin over the hernia was incised, and the structures overlying the sac were then carefully divided on a director until the sac was reached. The nail of the index-finger was then introduced under the edge of Gimbernat's ligament, and the stricture freely divided with Cooper's knife. The intestine was at once reduced, and a drainage-tube was inserted, and the edges of the incision were brought together by three silver wire-sutures. The wound was then dressed antiseptically, and the patient removed to his bed feeling much relieved.

After the operation all sickness ceased, and rapid reaction from extreme collapse set in. The extremities became warm, the pulse quickly improved, and the peculiar anxious expression of countenance soon faded away. The patient was ordered a grain of opium every fourth hour, and small quantities of milk frequently.

The morning after the operation the temperature rose to 99.5° F., but in the evening it was normal, the bowels having acted of themselves in the meantime. In a week the patient was out of bed, and the wound was quite healed.

Remarks by Dr. THOMPSON.—I have had many cases of hernia requiring operation, but unfortunately hitherto at least 50 per cent. of them have proved fatal; nor is this percentage, large as it undoubtedly is, in any way remarkable, for I feel convinced that if the statistics of operations for strangulated femoral and inguinal hernia were fairly

recorded, the unsuccessful as well as the successful, the mortality would at least reach the percentage I have stated. This excessive death-rate can, without doubt, be accounted for—first, owing to the common practice of opening the sac; and, secondly, the non-employment of Lister's antiseptic precautions. The case just recorded seems to demonstrate the advantages resulting from both these proceedings. There are of course cases which require the opening of the sac; for instance, where the hernia is an old one, and the strangulation has existed for many days, or again, if the intestine is gangrenous. In the former case there may be bands within the sac itself, binding down the intestine, and keeping up the symptoms of strangulation, even when the stricture has been freely divided. In the second case the sac must be opened in order to incise the gangrenous intestine for the purpose of forming an artificial anus. There can, I think, be no doubt that the modern practice of not opening the sac in recent cases of strangulated hernia is the right one.

Reviews and Notices of Books.

Practical Lithotomy and Lithotrity: or an Inquiry into the best modes of Removing Stone from the Bladder. By Sir HENRY THOMPSON, F.R.C.S., Surgeon Extraordinary to His Majesty the King of the Belgians, Emeritus Professor of Clinical Surgery, and Consulting Surgeon to University College Hospital, &c. &c. Third Edition, considerably enlarged. London: J. & A. Churchill. 1880.

THE worth of this treatise has been so well and long recognised that the work of a reviewer of a third edition of it is considerably simplified. Sir Henry Thompson's views, too, are tolerably generally known, for his annual course of lectures at University College Hospital and communications to our columns and various societies have enabled him to publish the fruits of his increasing and extensive experience. Although the whole of the work has been carefully revised and in several parts enriched for this edition, the chapters of most interest are that in which Bigelow's operation is discussed, and the final one, in which is a record of 500 operations for stone in cases of male adults under the author's care; such a table has never before been compiled by any surgeon. As we have recently drawn attention to Sir Henry Thompson's views on Bigelow's operation, as he expressed them at Cambridge, and as a *résumé* of the table of cases was presented to the Medico-Chirurgical Society two years ago, and commented on by us then, we need not notice them at length now. Suffice it that this edition is far more valuable to the practical surgeon than the last, and well worthy of the reputation of its accomplished author.

Leçons Cliniques sur l'Uréthrotomie Interne faites à l'Ecole pratique de la Faculté de Médecine de Paris. Par le Dr. DELEFOSSE, et recueillis par E. PROGEY. Paris: J. B. Baillière et Fils. 1880.

M. DELEFOSSE is an ardent advocate for the operation of internal urethrotomy, and in these five clinical lectures he has given forcibly and well "reasons for the faith that is in him." He regards dilatation as *par excellence* the treatment for stricture of the urethra; but in very nearly all cases in which it is impossible or difficult to carry it out, or in which it fails to give a thoroughly good result, he considers internal urethrotomy to be the best plan to be adopted. The use of caustics, which so long held their place in France, he rejects altogether, and he has nothing good to say of "rupture" or "forcible dilatation." He follows Civiale, Caudmont, and Thompson in preferring a urethrotome cutting from behind forwards to one acting in the opposite direction. Delefosse does not look upon urethrotomy as a mode of cure of an organic stricture, and he is at pains to point out what are the conditions most favourable to a slow recontraction of the strictured part. In his opinion they are, first, a complete division of the stricture tissue at one point; second, the ex-

istence of a layer of healthy elastic, supple, spongy tissue between the bottom of the wound and the fibrous sheath of the corpus spongiosum; and thirdly, the absence of inflammation in and around the wound, the occurrence of which is apt to cause a more rigid and contractile cicatrix. His after-treatment differs from that of English surgeons who have given most attention to this operation; for the first twenty-four to forty-eight hours he ties in a good-sized catheter, through which he allows the urine to drain continuously; by the end of this time the wound is glazed over, and the danger of urinary infiltration and the risk of primary adhesion of the lips of the wound avoided. After this he leaves the urethra quite alone for two or three weeks until cicatrization is complete, and then he completes the treatment by careful catheterisation. He points out that for any given case once urethrotomy, always urethrotomy. If recontraction occurs dilatation is of no avail to overcome it, but a repetition of the operation is necessary. There can be no doubt that internal urethrotomy is becoming more and more firmly established as a sound surgical procedure, and we think that its popularity is deserved. It is founded on correct principles, and promises to maintain its place. It is therefore especially desirable that it should be thoroughly understood and appreciated by the general surgeon, and that its performance should not be left in the hands of specialists alone. These lectures are, we believe, very honest, plain, and useful, and we welcome them as a practical contribution to a subject which, while attracting a good deal of attention now, is destined to do so far more in the future.

Fracture of the Patella. A Study of One Hundred and Twenty-seven Cases. By FRANK H. HAMILTON, A.M., M.D., LL.D., Surgeon to Bellevue Hospital, New York, &c. New York: Chas. L. Bermingham & Co. 1880.

DR. HAMILTON has chosen to study first all the cases of fracture of the patella that have come under his own care, and to those he has added all others that have been treated by his colleagues in the Bellevue Hospital of New York. He has not attempted to collect cases from all sources, and avail himself of all published experience; his object having been to study the general causes, course, and result of this fracture. A wider research would no doubt have given him a number of unusual cases; but taking the complete experience of one large institution, he has been able to avoid one of the most common statistical errors, and to present us with more trustworthy data. He is careful to point out that very many of the cases in which there is direct injury to the joint are really fractures by muscular force, and states that this is shown not only by a careful consideration of the history of these cases, but also by the fact that it is impossible to produce a transverse fracture of the patella by direct violence to the cadaver. Dr. Hamilton disapproves of Malgaigne's hooks and Dr. Hector Cameron's operation of suturing the fragments, but recommends a simple apparatus of his own, in principle like the simple inclined plane. He considers close fibrous union as the object to be aimed at, and remarks that bony union, even if possible, is not so strong as the ligamentous. In his experience refracture, or rather fresh separation of the fragments, has occurred in nearly every case quickly after the original accident, and he urges that great care should be taken to prevent its happening for three months, but after that its occurrence may be disregarded. Dr. Hamilton deprecates the employment of force in overcoming the ankylosis of the knee usually resulting, and recommends the joint to be slowly and carefully brought into use, and speaks of two years as the time in which the recovery may be looked upon as complete. Dr. Hamilton is too well known in this country as an authority upon fractures to require from us any support or

recommendation. This brochure is good work carefully and honestly done.

Life and Mind—on the Basis of Modern Medicine. By ROBERT LEWINS, M.D. Edited by "Thalassoplektos." London: Watts & Co. 1880.

HAVING no sympathy with the doctrines laid down in this book—full as it is of irrational dogmatism,—we would fain have set it aside without a word. It may perhaps be worth while just to indicate its tenor, which is that of pure materialism; although both author and editor (who has an appendix of his own exceeding the length of the original essay) lay down the law with so much confidence and self-assertion as to excite antipathy. Including in their onslaught the Christian, and, indeed, all religions, they demolish, no doubt to their own satisfaction, all the cherished beliefs of the majority of mankind. Nor do they spare even such rationalists as Huxley and Maudsley, but assail them for so far submitting to the English dread of ultimate analysis in confessing that there is something beyond our ken that science cannot solve. Assuming the unity of man, and basing their arguments upon cerebration as a function of organised matter, denying any ground for the hope of immortality or the existence of a Supreme Being, denouncing English timidity in refusing to accept the materialistic doctrines so prevalent in modern Germany, they profess to believe that the world will be better, morally, socially, and politically, as soon as their doctrines become universally accepted. And this is said to be the outcome of modern medicine! We do not, and will not, believe it; for we hold, that in restricting himself solely to the material, man unnaturally sets a boundary upon his intelligence, and enslaves himself even more than if he were to blindly accept the narrowest dogmas priestcraft has ever devised. It would be a melancholy thing indeed were such doctrines—which, in spite of the writer's denial, *must* inevitably lead to pessimism and all its evil consequences—to replace that surer trust based upon worthy aspirations after a better life, aspirations that are coeval not with the Christian religion, but with humanity itself.

THE SANITARY CONDITION OF MARGATE.

THE time has arrived when an energetic protest should be entered against the action, or rather the inaction, of the Margate authorities. This town occupies one of the most favoured spots in all England; it is frequented by thousands of visitors and hundreds of invalids, who come from all parts of the country. It has a duty, therefore, not merely to itself, but towards the visitors who enrich its inhabitants. Margate is so directly open to the north that a vessel steering north-half-east would reach no land before she coasts Greenland, in the latitude 75° N. Thus the wind from that direction may travel over 1380 miles of sea. Further, in consequence of the promontory Margate occupies, three winds out of the four pass over the sea before reaching it, and thus the climate is most bracing.

The white chalk soil, and the thin vegetable mould with which it is covered, enable the water to pass rapidly away. The dryness that results is also augmented by the scarcity of rain, for there are neither mountains nor trees to attract the clouds which often obscure the sky, but pass away inland. It is, however, unnecessary to insist further on the climatic advantages of Margate as a health resort; these have been fully vindicated over and over again, but the public at large have a right to protest against the impolicy of authorities who allow the benefits conferred by nature to be marred by the neglect of the most elementary rules of sanitation.

So far back as 1849 the town received a terrible warning. Dr. Chambers and others had in vain urged the necessity of sanitary reform, but it was only when the cholera broke out and killed 124 persons in one quarter, raising the death-rate from 18·5, which was the computed average at that time, to 29·5 per 1000, that some action was taken. A petition to the General Board of Health signed by 303 ratepayers brought Mr. Edward Cressy, C.E., down, who held an inquiry on the subject, and his report to the Board was published in 1850. Mr. Cressy recommended the laying down of sewers, the abolition of cesspools, of private slaughter-houses, and of piggeries within the town, the filling up of private wells, and the creation of a proper water-supply. During the course of thirty years that have elapsed since the cholera had inflicted so severe a lesson, only the latter of these suggestions has been carried out. Margate has a water-supply, though it is questionable if the water be safe from contamination.

In April, 1873, Dr. Gwynne Harries reported to the Medical Department of the Local Government Board on the sanitary condition of the town and the prevalence of certain kinds of disease. The picture given in that account should have sufficed to stir the authorities into action; but the grievances then denounced exist to this day. This damaging report has ominously been kept in the dark. Dr. Chambers, for instance, who has been twice mayor of Margate, had never seen a copy of it; indeed, so rare are the persons who have been privileged to read this report that there are actually rumours afloat of a supposed destruction of the documents.

The first and most prominent defect in the sanitary condition of Margate is what is known as the King-street sewer. This was originally built simply to carry away surface or rain-water. It joins a branch sewer from High-street, and has an outfall to the right of the jetty below low water-mark. A great number of houses, including some of the principal hotels, now drain into this sewer, and must suffer the natural consequences. Dr. Gwynne Harries describes it as of "peculiar, perhaps unique, construction, inasmuch as it rises 15 inches towards the latter part of its course, and thus forms a reservoir in which at least 15 inches of the thickest sewage is always retained. When the tide rises the sea pours down the sewer into this reservoir and drives back the sewage along the remainder of the drain, and sometimes out through the gratings."

Mr. W. Knight Treves, the Medical Officer of Health for Margate, in his report for the year 1875, protests, and has ever continued to protest, against this sewer. He compares it not only to an elongated cesspool, but to a bad cesspool, for it is built of old brick and is pervious. "At spring tides the sea forces back the sewage and causes it to overflow into the basements, and I have seen in this part of the town several of the basements flooded with some tons of liquid sewage." At its outfall the sewage occasions a nuisance at certain periods of the tide. The bathing, which is established on both sides of this sewer, is not so far removed as to be exempt from the probable presence of sewage in the water. At Ramsgate, where there is a similar outfall, the contamination of the bathing is acknowledged, and measures will, we are assured, be taken to prevent the evil.

The greater part of the houses in Margate do not, however, drain into sewers, but possess huge cesspools, which are special institutions in this part of the country, and find many advocates. These cesspools are dug out in the chalk to a depth of thirty, and sometimes even sixty feet. They receive the whole drainage of the house, with the exception of the rain-water, which is often collected in buckets for washing purposes; and, strange to say, the alleged virtue of these cesspools is, the inhabitants maintain, the fact that they readily allow all liquid matter to escape. This preposterous argument we found fully confirmed when we questioned persons in the habit of emptying the cesspools. One person, a plumber, declared that when his men had emptied a cesspool, he always went down in it to see that they had done their work properly. On our inquiring what he considered satisfactory, he replied that he made sure the sides had been "properly chipped." The grease from the kitchen waste and various other substances gradually clog

the pores of the chalk, and thus nature ultimately supplies what man should from the first have provided. The cesspool in time becomes water tight. But a water-tight cesspool means the necessity of frequent emptyings, and therefore of constant outlay, and such a result is viewed with no small displeasure by the householder. The plumber consequently plumed himself on his conscientious and disinterested action in rendering these receptacles of every sort of filth as leaky as possible. Not only are the sides "chipped" or scraped, but the bottom is generally dug out a foot or two deeper so that the plugging of the pores here also is removed.

We need not insist on the evils of such a system, they are universally acknowledged. In isolated country houses such cesspools would be bad enough, but in crowded, densely-populated streets they are a dangerous abomination. Yet this is the arrangement at Margate; some of the cesspools have been found even under the houses and the kitchens. In some instances the back yards are so small that the liquid matter escaping from the cesspools must pass under the houses, and the warmer atmosphere within these dwellings must draw the gases generated by this sewage filtration into the inhabited rooms and apartments. Of course, as was amply demonstrated in 1849, the neighbouring wells are contaminated, for the entire subsoil of Margate must be saturated with sewage matter. Ten years were, however, allowed to elapse after the outbreak of cholera before a general water supply was attempted, and even then this was not done by the town, but by a private company, and it was badly done.

A most unsuitable site was selected to sink a well. In a valley known as The Brooks the work was begun, and this on a spot which was probably a Danish burial-ground. In any case a number of human bones were among the first objects dug up. This unpropitious circumstance did not check the work; and when water was found, it was found at a level below that of the sea. Further, when a large quantity of water was extracted, the wells, for some distance round, were dried up, thus proving that the new supply was from the same water stratum as that which had already been condemned. This water has on many occasions been analysed, and though the reports vary considerably, they are, on the whole, decidedly unfavourable; indeed, considering the position of the source, any other result would have been very surprising. There are houses and leaking cesspools sufficiently near to account for anything; the cemetery also, though at some distance, is on a higher level and inland. It is also certain that the water does not invariably move towards the sea, but the rising tide forces it back towards the town well, rendering the supply not merely brackish, but bringing with the salt water some of the sewage of the houses that exist between the well and the sea. This is all the more blameworthy as, close at hand, in the Dane Valley, Professor Atfield indicated the presence of excellent water. Dr. F. Chambers has grouped together four of the reports that have been made in the following manner:—

One gallon contains—

	No. 1.	No. 2.	No. 3.	No. 4.
Total solid matter dried at 212° Fahr.	69	43	40	55
Free ammonia ¹	much	much	none	none
Ammoniacal, organic matter containing 10 per cent. of Nitrogen ¹	15·0	2·0	0·0	0·0
Albuminoid organic matter containing 10 per cent. of Nitrogen	2·25	1·60	·016	·161
Nitrites ²	none	much	none	none
Nitrates, containing 17 per cent. of Nitrogen ³	8·0	6·3	5·75	3·0
Chlorides, containing 60 per cent. of Chlorine	24·0	11·7	10·0	27·0
Hardness, reckoned as chalk, grains, or degrees removed on boiling the water.....	2·0	3·0	5·4	0·6
Unaffected by ebullition	6·5	4·5	4·0	4·0
Total hardness	8·5	7·5	9·4	4·6
Lead, none	0·0	0·0	0·0	0·0

¹ Taken together, No. 1 has a considerable quantity, and No. 2 much.

² Taken together, a considerable quantity.

No. 3 is water from the Dane valley. No. 4 is water from the Tivoli well.

Prof. G. W. Wigner, in 1877, analysed two samples of water, and found per gallon:—

	July 14th. Per gallon.	July 30th. Per gallon.
Chlorine, calculated as chloride of sodium	32.76	33.70
Nitrogen as ammonia	0.0025	0.0072
Albuminoid ammonia	0.0060	0.0045
Nitrates	0.8480	0.4220
Nitrites	0.0140	0.0080
Total nitrogen in these 4 forms	0.8705	0.4417
Oxygen absorbed by organic matter	0.0272	0.2500

In these two samples there was much suspended and vegetable matter. It is evident that the quality of the water varies considerably, according to the more or less intimate connexion between the drinking water and the enormous quantity of liquid filth purposely allowed to escape from hundreds of cesspools. As the town grows in size, and the number of cesspools becomes greater, so will this danger increase: and though the sewage matter undergoes a process of natural purification as it passes through the soil, still it is possible to over-tax this purifying agent, and the best filters, whether artificial or natural, are apt to become fouled.

So obvious are these facts, so pressing and present the danger, and so high is the death-rate at Margate, that the whole question has weighed heavily on the conscience of the town for many years. Lengthy discussions have been held, numerous schemes for draining the town have been drawn up, and finally the proposals of the borough surveyor, Mr. Albert Latham, were accepted, not only at Margate, but by the Local Government Board. Nevertheless years have already elapsed since this high sanction was obtained; but nothing has been done. The fact is that the scheme adopted is a somewhat expensive scheme. A portion of Margate lies so low that it is even below the sea-level, and it is indispensable to establish a pumping apparatus. The most difficult district to deal with is that known as the Marine-terrace. Here the street or esplanade was built after the houses, and these are so low down that they have two basements below the level of the street! Though apparently of but three stories they are really five stories; the drainage of these houses is into cesspools below sea-level, and constantly filled with sea-water. Immediately behind these houses the valley of the Brooks stretches out, and at a point called Tivoli is the well whence the town water-supply is derived. It is difficult to account for the presence of sea-water at Tivoli unless it has first passed by the cesspools in and about Marine-terrace.

The Town Council has just purchased for the great sum of £59,000 the plant and good-will of the Waterworks Company, and as a responsible public body, mindful of the health and life of their constituents, it is to be hoped that they will at once remove their pumping apparatus, &c., either to the Dane Valley or some other spot, where pure water can be obtained. It is equally urgent that the work of laying down sewers and properly draining the town should also be promptly commenced. By the accepted scheme the entire sewage of Margate and Cliftonville would be carried away to the Long-nose—Spit Rock, off the Foreness Point. For this purpose an outfall tunnel some 8000 feet long will be necessary. This will, or should, do away with all cesspools, and with the abominable drains that we have described falling into the sea near the jetty, and with the smaller drains of the Buenos Ayres district, that also fall into the sea objectionably near to the bathing and beach.

In the meanwhile there are smaller but also urgent reforms that could be at once carried out. The presence of piggeries within the town is a most offensive nuisance. A number of private slaughter-houses are badly managed; there is nothing to prevent the filth from them soaking into the soil. The Act, also, with respect to the management of dairies is not carried out, and apparently no one seems inclined to make it his business to enforce the excellent regulations laid down by the law. At the same time, we must give the Sanitary Inspector credit for a display of considerable energy. No less than 113 notices to abate nuisances were served during two weeks in August of this year, and many cesspools are now ventilated.

Nevertheless, considering the climatic advantages that Margate enjoys, the death-rate is high. This is due in some measure to the fact that during the season the inhabitants let

the better part of their houses as lodgings, and crowd down in the basements. Here the children are kept in close proximity with the sink, and its untrapped pipe leading to a cesspool, which is perhaps only emptied once in ten years! The infant mortality is consequently excessive. In the year 1878, for instance, the infant mortality at Margate was at the rate of 184 to 1000 births, as against 153 in all England!

The death-rate of Margate is estimated in a manner peculiar to itself. We were presented with what is called a corrected average, but in this the corrections are all on one side. The deaths taking place at the hospitals, at the Infirmary for Scrofulous Disease, and even at the Union work-house, are deducted. Nor is this all; even the visitors that die at Margate are not included. Nothing, on the other hand, is said of the deaths that occur at the Fever Hospital, which happens to stand within the Ramsgate district, though built for both towns. Apparently the fever cases removed from Margate to this hospital figure in the Ramsgate death-rate. Also it is evident that a great proportion of visitors, on the first symptom of disease contracted at Margate, hasten back to their homes, and thus for the most part augment the London death-rate, when in reality the bad sanitation of Margate is to blame. No allowance is made for this, and it is therefore not fair to compare the so-called corrected death-rate of Margate with that of other towns. Still, even when taken at the best, the figures are not over favourable. Thus, taking the reports of the medical officer of health—reports, by the way, which are only printed when they are considered favourable, and which therefore we had in some instances to read in the manuscript—we find that in 1875 the gross death-rate on the population—11,956—was 23.75 per 1000. The corrected estimate allows for an increase of population only, and amounts to 20.41; the zymotic death-rate being 3 per 1000. Dr. Gwynne Harries in his reports remarks that in 1872 the zymotic death-rate reached 3.8 per 1000, and that seven only of the forty-three English watering-places had a larger proportionate mortality from this cause. In 1876 the gross death-rate was 18.81, but by estimating the population at 13,000, and deducting 30 scrofulous persons who died in the hospital, and 10 visitors, we have a corrected death-rate of 14.23. The zymotic rate was 2.53. In 1877 the gross death-rate is given on a population of 13,500, and not on the census estimate, and it amounts to 18.81; from this 41 deaths in hospitals and 53 among visitors are deducted to produce a corrected average of 11.85. The zymotic rate was only 1.85. In 1878 the gross rate on a population of 14,000 was 21.35; the rate corrected as above was reduced to 17.28. The zymotic rate was 3.5. The average for these four years would be a gross death-rate of 21.18; the corrected death-rate was 15.94, and the zymotic rate 2.72. Nor are these four years exceptional years. They are better than many previous years, though there was a limited outbreak of scarlet fever in 1878.

Considering the bad sanitary condition of the town, these figures are a proof of the counteracting and purifying influence of the climate and winds. Still, for a town so exceptionally placed as Margate, they are anything but satisfactory. Indeed, this would be a good opportunity for interference on the part of the Local Government Board. This body might, at least, insist on the immediate execution of the drainage scheme it sanctioned three years ago, and on the proper supervision of the dairies, &c. The Harbour Company were sentenced in the Court of Queen's Bench to keep the harbour clean, but this is still a great nuisance every time the tide is down, though the decomposed seaweed laid bare would, if removed, make valuable manure. Margate, unfortunately, is a sedentary town, and will not move unless under severe pressure. This town actually fought against railways and against steamers. It would not allow the South-Eastern Railway Company to establish the coaling station here, which has since become the fortune of Whitstable. It resisted the creation of the jetty, which is now the glory of the town. In a word, every form of progress has been energetically resisted by the inhabitants of Margate. Whatever has been done, has been done long after other towns have set the example, and, therefore, it is not surprising if, in sanitary matters also, Margate should be behind the age.

THE net proceeds of the Hospital Saturday collection at Lincoln amount to £90 8s. 10d., £60 5s. 10d. of which is to be paid to the County Hospital, and £30 3s. to the Leeds Eye and Ear Infirmary.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 25, 1880.

THE nineteen bodies which compete with each other in the business of licensing men to practise medicine within the bounds of Her Majesty's dominions should be more eager than the profession itself for the amendment of the Medical Act. Mr. SIMON in a memorable speech in the Medical Council tried to impress that self-complacent body with the urgency of the question of medical reform by referring to the schism in the profession caused by this question. But to our thinking there is a more powerful appeal still to be made to the nineteen bodies, and that is the schism which exists among themselves. It is true that when the meeting of the Medical Council comes round, the common sense of living in a glass house makes the members all very courteous and considerate towards each other. The love of privilege and existence in them all, and in each of them, secures a sort of common action towards the preservation of each, and of each other. But it remains true that there is a kind of schism in the bodies. They disagree. They misrepresent each other; or, to use the lightest phrase, they misunderstand and distrust each other. This disagreement and mutual disparagement are a scandal incident to, and inseparable from, the present licensing system, and constitute a powerful argument against the system. If we can prove that the scandal exists, and that it is inseparable from the existing system, we shall hope—though it be against hope—to convince those who advocate the system that their great interest lies in a modification of it, and that their interest in such a modification is greater than that of anybody else.

We have, then, to prove the existence of a scandal in the present licensing system, and in the mutual misunderstanding and disparagement which it involves. We shall have no difficulty in doing this out of the mouth of witnesses whose authority will be admitted by both the Medical Council and the various Licensing Bodies in the several divisions of the kingdom. The authority we shall first quote as to the existence of a scandal in the present licensing system is that of a Committee of the Medical Council, representing each Royal College in the three kingdoms, and the Scotch, Irish, and English universities, the chairman of which was Dr. ANDREW WOOD. The language of this committee was as follows:—

“One of the great evils at the present moment is the inequality of the examinations for licence. This inequality of the test of efficiency is the more unfortunate as every licence confers an equality in the right to practise everywhere. The easy examination of one licensing body tends to depress the standard of the examination in all the rest. Visitations of examinations doubtless partly remedy this state of things, but to completely remove it a bolder course is necessary.”

The report then goes on to indicate the necessity for such a combination of the Licensing Bodies as may form a Conjoint Examining Board, and to indicate the probability of having to apply to Parliament for powers to effect such a combina-

tion. Twelve years have elapsed since this report was drawn up by a Committee of the very greatest weight and authority. The inequality remains, and is a scandal.

But the scandal to which we wish at present more particularly to allude, is the disposition to blame each other evinced by the various bodies and the light in which they have placed each other before Parliament and the public. It is one thing for the bodies to think meanly or disparagingly of each other, and another for them to discredit each other before Parliament, and then quietly to retire from the scene before asking for Parliamentary remedy and securities against the evils which they have described. England blames Scotland and Scotland retorts on England, and both blame Ireland, till statesmen must feel considerable surprise that honourable men should be amongst the defenders of a system under which such charges and insinuations can be made. Let us consider a few of the things that have been said by prominent witnesses before the Select Committee, and which are a part of the indelible evidence before Parliament. Mr. SIMON said the number of cases of gross ignorance passed by the Licensing Boards, and detected by the Army and Navy Boards, were a very serious blot on the system, and showed clearly and decidedly that there was slackness in some of these examinations. Referring to the examination for the degree of Bachelor of Medicine in the University of Edinburgh, to which Professor TURNER justly attaches very great value, Mr. SIMON coolly said:—“I have no reason at all to suppose that it is higher than might properly be the general examination for Scotland.” To question 785: Is there any tendency on the part of candidates to run to the easy gates of admission? Mr. SIMON said: “I can hardly suppose the contrary.” Sir JAMES PAGET, in his own delicate way, said: “There is a general belief that some of the examinations both in Ireland and Scotland are not so high as they might be. I do not hear it stated that they are so low as to be unsafe; but it is believed that some of them are not so high as they might be.” Before he left the Committee Sir JAMES PAGET had to confess that the examination of his own College was most indefensibly defective, and did not include Chemistry, Midwifery, Materia Medica, Pathology, and Jurisprudence. When the Scotch witnesses came before the Committee they were not slow to retaliate. Professor STRUTHERS charged Mr. SIMON with being unacquainted with the existing state of things. Professor GAIRDNER, referring to some hazy and vague language of Dr. ACLAND's as to the conditions of graduation at Glasgow, described Dr. ACLAND's state as one of invincible ignorance, or marvellously shutting his eyes to facts; and, referring to the examination for the membership of the English College of Surgeons, said: “England, in this respect, is alone among civilised countries; there is no civilised country in the world except England where it has been quite the habitual thing for a man to go out with a licence in Surgery and not to be examined in Medicine, or Midwifery, or Materia Medica; and there are hundreds of such men in the country now.”

Such are a few of the amenities exchanged by the rival witnesses before the Select Committee. Is it creditable that they should be willing to let all things continue as they are, and to take no step to satisfy Parliament and the public that they are doing their very best to remove all the inequalities

and supply all the defects which create mutual distrust, and constitute at the present moment a scandal in the eyes of Parliament? The Bodies themselves—this is our contention—have the greatest possible interest in demanding legislation that shall equalise minimum examinations and suppress that whisper of disparagement which has been heard in Parliament and which will be heard again till the system of Licensing and the Constitution of the Medical Council are altered. The examining system is no longer a parochial or territorial one. The meanest qualification of the lowest body carries Imperial privileges, and should be above suspicion.

THE proceedings that have recently taken place at Cork, whereby the treatment of a physician has been impugned, are too serious to be passed over in silence, for they involve matters of much importance to the profession, which in the person of Dr. MACNAUGHTON JONES has been so unwarrantably attacked. They took place, too, at a court of inquiry in which evidence was taken without the protection of an oath; where random and irreconcilable statements were made; where a leading solicitor of the town was opposed, with all the advantage of professional skill, against Dr. JONES, who had to conduct his own case heavily weighted, which he did with commendable vigour, conscious of the right on his side. His position was indeed an unenviable one, but we are proud of the manner in which he managed his case and met the aspersions on his character. It is well known how Dr. MACNAUGHTON JONES has won for himself, by sheer force of energy, a high position in the profession. His name is known not only in the city of Cork, but throughout the United Kingdom; and many will endorse the gratifying testimony of the high estimation in which he is held, given by Dr. DENIS O'CONNOR, the Nestor of the profession in that city, who last year held the honourable office of President of the British Medical Association.

With the evidence before us—and it fills the columns of the local daily journals during a whole week—we are amazed at the character of the inquiry. With scarcely an exception, there has never been so vexatious, so uncalled-for, so cruel a persecution of a public officer as that to which Dr. MACNAUGHTON JONES has been subjected. We would that we could say the case was wholly without parallel; but with regret we recall how, a few months ago, a member of the profession had to defend himself in a court of law in a somewhat similar manner. The occasion which called for the prosecution in that case was substantially the same as in this, although the circumstances were different. In the case at Westminster the same spirit seems to have been at work: the feelings of a bereaved parent (in that case unfortunately a brother practitioner) were aggrieved. Dr. MACNAUGHTON JONES has emerged from this inquiry with his character fully indicated and his course of action justified; but the pity of it is that he should have had to endure the anxiety and mental strain entailed by most painful proceedings. We will endeavour to put our readers in possession of the facts of this case, which is full of lessons to the medical profession and to the public.

So far as can be gathered from the mass of evidence—some of it very contradictory—the following is the history of the case that led to this prolonged inquiry, eight months afterwards. In the month of February last, a Mr.

CRAWFORD, schoolmaster, had the misfortune to lose two children from scarlet fever. A third child sickened, and the father was strongly urged by Dr. JOHNSON, who saw the case, and diagnosed it as scarlet fever, to send the boy to the Fever Hospital, where a certain number of wards are reserved for paying patients. The staff of this hospital consists of Drs. BEAMISH, JONES, and BUDDS. Mr. CRAWFORD demurred at first, but in yielding he asserts that he stipulated that the child should not come under the care of Dr. JONES, alleging as his reason that he knew Dr. JONES was an enthusiast for experimentation, and "he would not have his child experimented on." It was suggested that the patient should go into the same ward as his sister-in-law, who was under Dr. BUDDS, also for scarlet fever; but to this proposition it would seem Mr. CRAWFORD—who appears to have acted throughout in the most impracticable manner—also objected; and the result was that the child was admitted in the ordinary way, and fell under the care of Dr. JONES, who saw him the morning after his admission, who recognised the gravity of the case—it was one of suppressed malignant scarlet fever—and who prescribed, amongst other remedies, wet packing and the subcutaneous injection of pilocarpin. A few hours later the father, who had heard of the measures proposed, meeting Dr. JONES, requested that another physician, who had no connexion with the hospital, should be called in consultation. This of course was out of the question, and Dr. JONES, not suspecting the real reason of this strange request, told Mr. CRAWFORD so, but offered to hand over the case to, or to consult with, one of his colleagues if the father wished it. But Mr. CRAWFORD expressed himself satisfied. Meanwhile, some difficulty had been experienced in obtaining a solution of pilocarpin of the required strength, and the injection was not administered until Dr. JONES came and gave it himself at the end of the afternoon. The patient was then very ill, and it was evident that the remedy could only be adopted as a *dernier ressort*. The drug produced its usual effects, free diaphoresis, increased bronchial and salivary secretion, &c.; but in spite of stimulants the child died the same night. There are several points which seem to show want of judgment on the part of the resident officer, and bad management generally, but the above are the essential features of the case. There were contradictory statements as to whether Dr. JONES did or did not leave instructions to be sent for if the symptoms grew worse; at any rate he was not sent for, and only knew of the child's death on going to the hospital next morning. The father now alleged—first, that Dr. JONES had not shown care enough; and, second, with strange contradiction, that he had been too energetic in his treatment of the case. He caused an inquiry to be set on foot at the hospital itself, but as the proceedings there were not made public, he entrusted the case to one of the leading solicitors of Cork to formulate specific charges, and at the meeting of the Town Council on September 6th, his solicitor attended to oppose the usual grant to the Fever Hospital on the ground of these charges. After all the facts had been laid before the Town Council, a resolution was carried instructing the managers of the hospital, of which the Mayor is chairman, to hold another inquiry into the matter, and to report to the Council; an amendment by Dr. CREMEN,

expressing confidence in the management and in the inquiry already held, being withdrawn. On September 9th the inquiry was opened; and after public sittings of upwards of five days, during which the whole miserable business was raked up to the full, the committee reported its decision on the 18th. We regret that the inquiry elicited facts which showed that the hospital management was defective in more than one point—to which we shall presently advert.

The charges formulated by Mr. CRAWFORD ran as follows:—1. That having received a distinct promise that his child would not be placed under the care of Dr. JONES, he was subsequently so placed. 2. That Dr. JONES, having refused to allow his (Mr. CRAWFORD'S) private physician to be taken into consultation as to an operation proposed on his child, subsequently performed that operation (a new and dangerous one) without consulting his own colleagues in the hospital. 3. That he performed that operation without any proper explanation to Mr. CRAWFORD of its nature or effect, and without getting his sanction. 4. That he exhibited want of care and discretion as to the time of performing the operation, and great carelessness and neglect subsequently, considering the dangerous and novel nature of the operation.

Upon the first of these charges most contradictory statements were made, and there is only Mr. CRAWFORD'S evidence in support of the allegation. Dr. ADDERLEY, the resident medical officer, who upon some other points was in harmony with Mr. CRAWFORD, gives quite a different version of the supposed request and stipulation, averring that the father demurred to the child being placed under the care of Dr. BUDDS, and yet appeared satisfied when told that it would be admitted in order, and would come under Dr. JONES. The complainant said that at his request Dr. JOHNSON wrote to Dr. BUDDS about the case, but the letter was never sent, because, Dr. JOHNSON says, the child did not come under Dr. BUDDS' care. The charge, however, foolish as it is, gives a clue to the whole of this pursuit of Dr. JONES. From the very first Mr. CRAWFORD distrusted that gentleman, and it may well be imagined that his preconceived opinion dominated throughout, and made him attribute the child's death to its having been under the care of a man whom he mistrusted.

The second charge is the gravest; and the one which carries with it the issues most important to us as a profession and our relations with the public. It consists of at least two points. The first is that Dr. JONES refused to call in consultation upon the line of practice he was about to adopt in the case the "private physician" of Mr. CRAWFORD. This gentleman must have been strangely ignorant of hospital management if he supposed the procedure he suggested could be carried out; but we fear he was encouraged in this request by being told by Dr. ADDERLEY that there was a precedent for him to follow; that Dr. HARVEY had once attended his servant there and prescribed for him, the truth being that Dr. HARVEY only saw the case as any visitor might. It would be absurd and intolerable were this principle of extraneous consultation to be put into practice. A hospital management provides itself with its own staff, and has full confidence in its members, knowing that they are well able to cope with the diseases before them; and the idea of introducing further medical opinion to suit the caprices and whims of the patients'

friends is one which has never, we believe, been before broached. It was said that on hearing this request Dr. JONES should have perceived that the child's father had lost confidence in him, but, on the contrary, he expressed himself satisfied, and would not consent to Dr. JONES'S proposal to transfer the case to one of his colleagues! The other count of this charge was that Dr. JONES had performed a "novel and dangerous operation" without consulting his colleagues. That the hypodermic injection of a solution of pilocarpin should be so described is ridiculous. As Dr. JONES clearly showed in his admirable statement, that drug has for some years been used in many diseases, among them scarlet fever. Never were clearer indications given for its use than in the present case; and if once the principle be admitted that the employment of a powerful remedy in a desperate case is to lay the physician open to a charge of malpraxis, all hope of advance in medicine is gone. But we may ask, How was it that Mr. CRAWFORD knew of the intention to employ this drug? what ground had he as a layman to question the procedure, or to allege that it was dangerous? We regret to find it recorded that he obtained this information from Dr. ADDERLEY, who is said not only to have shown him the prescription, but to have intimated that the remedy was a new and untried one, and is further said to have added, that he himself would be afraid to use it. Such an expression of opinion was clearly enough to have disturbed the equanimity of even a stronger man than Mr. CRAWFORD has shown himself to be. Backed up by such a preposterous statement from the resident medical officer, no wonder he felt himself justified in the course he took, magnified the administration of a hypodermic injection into an "operation," and imagined that so grave a step should only be taken after consultation.

Upon the plea that pilocarpin was a new and dangerous remedy, Dr. JONES was, of course, enabled to bring overwhelming evidence in reply. He showed how grave the case was; how such a type of scarlet fever invariably ran a fatal course; how pilocarpin had been advised by some authorities and prescribed by others in like circumstances; and, in a word, how its use was almost the only resource left him to employ. He was supported in his argument upon the nature and uses of pilocarpin by the evidence of Dr. GAVAN DUFFY of Dublin, and by letters from distinguished practitioners. The "prosecution" endeavoured to urge that the drug should have been given by the mouth, and not injected under the skin (or into the veins, as they stated!); that jaborandi should have been given, and not its active principle; but confutation of this special pleading was easy enough. Nor could it be alleged that the injection was not given with the greatest care and caution. Pilocarpin is one of the most powerful drugs of its kind, and most certain in its action; and its employment in such a case as the present was rational and scientific. No time could be lost, and the desperate nature of the case demanded the administration of a rapidly and powerfully acting remedy. What would have been said, it was pertinently remarked, had Dr. JONES contented himself with letting the patient die without trying all the measures known to him? Was he to be blamed because his knowledge was of a wider scope than that of others? The case is another illustration—too common it is to be feared—of

the vulgar ignorance which would rather see the approach of death than sanction the employment of the only means which may avert it, because of a supposed "heroic" character. The father would have felt differently had Dr. JONES succeeded by these means in rescuing the child from death. But are still living in the age of unreason! As to the lack of consultation with his colleagues before giving the drug: it might have been prudent had this course been pursued; but the proposal does not seem to have been entertained at all, for consultations were not the rule at this hospital. Dr. JONES acted on his own responsibility, secure in his knowledge. His action was scientifically right, and there was really no more reason for consultation than there is in the treatment of every patient that comes under the care of a medical man.

The third charge is equally preposterous, and may be dismissed in a very few words. It is not the duty of the physician to explain every step of treatment of a case to the relatives of a patient, and to get their sanction for such treatment. It is enough for them to know that no means will be left untried in averting the fatal result; and to imagine that before such measures could be taken they should be consulted and their approval gained, is too absurd to be dwelt on. So, again, with the final charge, which accuses Dr. JONES of want of proper care and discretion. It was urged that the administration of the drug was postponed till it was too late to have any good effect. Some delay was, it seems, experienced in obtaining the drug, but its administration was left until Dr. JONES himself gave it, eight hours after he had first prescribed it. So again with his other orders,—the "packing" was not commenced until after this second visit, and the child does not appear to have had the stimulant Dr. JONES ordered. There was also a discrepancy as to whether Dr. JONES had left instructions to be sent for if the symptoms grew worse, or not—the result being that, after the pilocarpin was given, he heard no more of the case until the next morning, when he learnt that the child had died in the night.

As may be imagined, the Committee could have no difficulty in arriving at a decision, in spite of the able manner in which Mr. JULIAN, the advocate, conducted his case. They saw clearly that Dr. MACNAUGHTON JONES had acted with full cognisance of the responsibilities of his office, and yet they could not but see that there was something radically wrong in the working of the hospital. This, indeed, came out so plainly at the inquiry that Dr. O'KEEFE sent a letter, which was read in court, maintaining that unless improvements were speedily effected, the Fever Hospital had better be closed. The Committee found that Mr. CRAWFORD had good reason to believe that his child would not be placed under Dr. JONES's care, but that Dr. JONES was in no way involved in the matter, and that he was quite justified in refusing to take Mr. CRAWFORD's private physician into consultation. They did not think that the term "dangerous" was applicable to the drug administered in the case. They regretted that Dr. JONES did not take his colleagues into consultation, but the medical evidence showed that from Dr. JONES's special knowledge of the drug he was warranted in dispensing with the consultation. They did not think it was necessary for Dr. JONES to give

an explanation to Mr. CRAWFORD as to his intention to use the drug. Finally, as to the charges of negligence before and after the application of the remedy, want of care as to the time of performing the operation, and lamentable delay in its application, they considered that there was evinced an absence of sufficient care and interest in the treatment of the case. The Committee also expressed their intention of at once attending to the improvement of the management of the hospital.

Thus has ended one of the strangest inquiries that has ever been set on foot. Dr. JONES has been treated with scant courtesy and great injustice, but he has come out of the matter triumphant, and has thoroughly vindicated the rights of hospital medical officers, whose position and responsibilities should surely entitle them to be protected from misrepresentation. Fortunately, this is an uncommon occurrence, for the office of a hospital physician would be intolerable were his practice liable to misconception on any occasion when he is called upon to treat his patients independently. We are sure that the public will, no less than the profession, see that it is impossible for a hospital to do its work unless the fullest confidence is reposed in the medical officers.

A CORRESPONDENT, Dr. IRVINE, of Pitlochry, sends us an account of a curious method of treatment of the bite of a rabid dog. A boy was bitten by a dog, and severely lacerated on the face. There were three deep cuts, one requiring a stitch. In order to preserve the boy from the possibility of hydrophobia, the friends had adopted the following precaution:—They wiped all the saliva they could get out of the dog's mouth, rubbed this well into the cuts, and then shot the dog! It is a common belief among the peasantry of the district that this procedure will infallibly prevent the bitten person going mad. Our correspondent rightly points out that the measure constitutes a grave danger to the public, and is, indeed, a public disgrace. We think that the local authorities of the districts in which such a custom is practised should do something to diffuse a knowledge of its extreme danger. If a person were bitten through clothes (so that the saliva were wiped from the biting teeth), and then the saliva of the dog deliberately rubbed into the wound, and death from hydrophobia resulted, the person rubbing the saliva would almost certainly be responsible for the resulting death.

In his Gulstonian lectures Dr. GOWERS pointed out the identity of some of the symptoms of hydrophobia and hystero-epilepsy, that one effect of the poison of rabies seems to be to produce a transient hysteroid state, while, on the other hand, in the paroxysms of hystero-epilepsy there may be barking and biting in a curiously animal manner. This is no doubt the true explanation of a case which came recently under the notice of a police magistrate, and has furnished some of our lay contemporaries with a subject of discussion. A boy had suffered from epileptic attacks for some time, attributed to the bite of a dog two years previously. In these attacks, which recurred every evening, he would bark and bite, and his father was convinced that he was suffering from hydrophobia, notwithstanding the assurance to the contrary of some medical men who had seen the case, and the fact that the dog which had bitten the

boy was still well. From the accounts which appeared in the daily papers the nature of the affection is obvious.

Another case in which the same diagnostic problem arose has been reported from Buckinghamshire. In this, even a medical man appears to have been misled as to the nature of the disease. A boy, whose mother was epileptic and insane, was seized with a peculiar attack. Previously well, he one day "fell off his seat and commenced jumping about the room like a frog. He snapped at everything, even flies, and getting hold of a cap, tore it to shreds. He also barked and acted like a dog gone mad, and it took two men to hold him from the time he was seized with the fit until half past five." A doctor pronounced the case to be one of hydrophobia. The boy was removed to the Maidenhead Infirmary, where nothing could be found to be the matter with him. The lad himself only remembered feeling giddy, and then nothing more till he found himself in the hospital. This was clearly a case of an epileptoid seizure with post-epileptic hysteroid or maniacal symptoms of the character to which DR. GOWERS has called attention.

A case of hydrophobia, in which accidental circumstances rendered the diagnosis at first one of some difficulty, was described to a recent meeting of the Académie de Médecine, by M. HARDY. On August 18th he was asked, at the house of a patient whom he was visiting, to see also the coachman, who had had some painful symptoms since an attempt to move a heavy carriage a few days before. Feeling great pain in the arm immediately afterwards he had it tightly bandaged. In consequence of the compression the hand and forearm swelled and became livid and very painful. During the next two nights a new symptom came on, a sense of constriction in the chest and throat, occasional hiccough, and an inability to drink. At the same time the patient was restless and could not sleep. M. HARDY found him with a normal pulse, but with sunken eyes and anxious countenance. On being offered water in a glass or spoon the man threw back his head, closed his teeth, and was seized with spasm in the throat. It was ascertained that four months previously he had been bitten on the finger of the left hand by a small dog which was constantly with him, which slept in his bedroom, and was usually very quiet. On that day, however, it suddenly became troublesome, bit its master, and then ran away, and had not since been heard of. Two months and a half later, another dog in the house became ill, and a veterinary surgeon, to whom it was taken, pronounced it rabid, and poisoned it. It could scarcely be doubted, on these facts, that the coachman was suffering from rabies. Chloral was given by the rectum, an injection of morphia was administered by the skin, and the constant current applied to the throat. Under the latter the spasm ceased at once, and for some hours the man was able to drink. Forty-eight hours after the onset, however, convulsions came on; he endeavoured to get up and go away. Seven or eight assistants could scarcely keep him from jumping out of window. After several similar attacks he became weaker, and died on the third day. M. HARDY raised the question whether the pain suffered in consequence of the injury to the arm may not have acted as the excitant of the symptoms, and also remarked that the period of incubation in the man was, in this case, nearly double that in

the dog; and, lastly, pointed out the lesson, taught by so many cases of the disease, that suspicious symptoms in familiar dogs should be met by the same precautions as would be adopted in the case of strange animals. M. BOULEY also insisted on the importance of the diffusion of a knowledge of the early symptoms of rabies. In the case under discussion, in a household in good position, characteristic symptoms had been quite unnoticed. He mentioned a curious instance of the manner in which such things were managed better out of France than in it. When on a visit to Bavaria, to one of the councillors of the district, in 1866 or 1867, he found himself one day an object of great interest to a troop of children coming out of school, and he ascertained that at this school the children had been made to learn by heart a report on the early symptoms of rabies which he had presented to the Académie in 1862. The example might be followed with advantage elsewhere, and it seems probable that it will now be followed in France. M. BOULEY mentioned another instance of the value of the constant current in the paroxysms of spasm. A young veterinary surgeon in La Capelle, suffering from rabies in consequence of the bite of a dog, and violently convulsed, was treated by a constant current from the nape of the neck to the soles of the feet, and immediately all the phenomena of dysphagia ceased, and the patient recovered the power of drinking.

Another case of hydrophobia, which has lately occurred in Paris, was also that of a veterinary surgeon. He had been bitten at least twice previously by rabid dogs, but on each occasion the bite was in soft parts, where it could be immediately and efficiently cauterised. The last bite, which caused his death, was near a finger-joint, where there was no adipose tissue beneath the skin; and the cauterisation, first with nitrate of silver and then with nitric acid, was probably insufficient—at least this was the opinion of the unfortunate subject of the disease. The period of incubation in this case was three months.

These are the only two cases of hydrophobia which have occurred in the Department of the Seine since the commencement of the present year, although twenty-four persons are known to have been bitten by rabid dogs, and no less than 127 dogs have been killed as distinctly rabid or as presenting suspicious symptoms, and 103 dogs destroyed in consequence of their having been bitten by rabid animals.

Annotations.

"Ne quid nimis."

GUY'S HOSPITAL.

THE state of civil war at this hospital continues. At the meeting of St. Saviour's Board of Guardians on September 17th Dr. Iliff drew attention to the subject, upon a letter from Dr. Rendle, of Forest Hill, urging the Board to intervene between the Governors and the medical staff; and an extract from a letter written by one of the staff was enclosed, stating that the medical staff and the governing body were "more at loggerheads than ever." Dr. Iliff referred to the changes that had taken place in the nursing arrangements, and defended the old nurses from the aspersions cast on them; and after referring to the case of Ingle, which, he imagined, would have led to some alteration in the

arrangements, he moved that a memorial should be sent to the Governors, setting forth that the Guardians had heard with regret the differences between the Governors and the medical staff on the nursing question, and of the determination of the former to make the latter subordinate to the nurses, which could but result in great injury to the patients. They had also heard with regret the attacks made upon the old nurses, but were not without hope that the Governors would yet see their way clear to modify the present system, so that all concerned might work more harmoniously. The chairman, in seconding the resolution, said the memorial would call the attention of the Governors to the fact that they were subject to the opinion of the public. Mr. Robins was of opinion that the memorial did not go far enough, and intended to move at the vestry for a petition praying for an inquiry into the whole system. Mr. Williams would have liked the memorial to be more severe. It was unanimously agreed that the memorial should receive the seal of the Board and be forwarded to the Governors. We are glad to see this awakening of the public mind to the continuance of this scandalous state of affairs; and we are at a loss to conceive how the governing body can persist in their line of action in the face of an opposition which is by no means limited to their own medical staff. A letter from Sir Thomas Dyke Acland appears in our issue to-day on the present position of the nursing question at Guy's and elsewhere.

EXPERIMENTAL DIVISION OF THE OPTIC AND CILIARY NERVES.

THE effect of division of these nerves, separately and together, has been studied experimentally by M. P. Redard, on rabbits and dogs. The ciliary nerves were divided alone, chiefly upon dogs. The nerves are distinctly sensitive. After complete division the cornea had lost all its sensibility, and its transparency quickly disappeared. The pupil dilated. In rabbits the dilatation of the pupil was preceded by a transient contraction. If the section of the nerves is partial, the anaesthesia and paralysis of the iris are also partial. The pupil becomes irregular. When the outer ciliary nerves are alone divided, the outer part of the iris is alone paralysed, and the inner part still contracts under the influence of light. The division of the nerves did not, in these experiments, lead to any disturbance in the nutrition of the cornea or of the eyeball, unless the injury and hæmorrhage produced by the operation were very great. The dilatation of the pupil continued for four or five months, but the sensibility of the cornea returned in about three months, at first locally, afterwards generally. Several animals were exhibited to the Société de Biologie in which the ciliary nerves had been divided a year and a half before, and the sensibility of the cornea was perfect. The circulation in the optic papilla was disturbed soon after the operation. Sight was impaired at the commencement, but complete blindness was never observed. In some there appeared to be no disturbance of sight. In a few cases there was distinct optic neuritis, with partial consecutive atrophy, irregularity of the edges of the papilla, and dilatation of the veins.

If both the optic and the ciliary nerves are divided there results, of course, immediate insensibility of the cornea, and enormous dilatation of the pupil. The fundus oculi and papilla are pale, but some veins remain gorged with blood. Trophic changes often lead to failure of the operation; the cornea becomes perforated, and the eyeball undergoes atrophy. This happened with especial frequency when the blood effused in the wound hindered union of the divided structures, or when the upper part of the eyeball had been laid bare in the neighbourhood of the insertion of the superior rectus. This effect was attributed to the division

of the anterior ciliary vessels. In the majority of cases, however, the nutrition of the cornea, and the shape of the eyeball, were not affected. Black hæmorrhagic points were seen near the disc, and some patches of choroidal atrophy. The pupil remained dilated, and only at the end of about six months did it recover, in slight degree, its contractility. Corneal sensibility returned in three or four months. In the animals shown, which had been operated on a year and a half previously, it was almost perfect. The ciliary nerves appeared to have undergone almost complete regeneration.

THE PROVIDENT DISPENSARY MOVEMENT IN MANCHESTER.

THE most important development of the Provident Dispensary Movement of late years has been the attempt to establish them on a large scale systematically in Manchester, Liverpool, Birmingham, &c. The *Manchester Guardian* contains a report of a meeting of working-men in the dining-room at the Ashbury Carriage Company's works in connexion with the new branch of the Manchester and Salford Provident Dispensaries Association. Dr. John Watts delivered an address, in the course of which he said there were now four Provident Dispensaries in the city that were paying their expenses entirely, and wanted no contributions except from members. Two others were just upon the edge of self-support, and a seventh was making very fair progress, but it was not yet a year old. The Council wished to establish an eighth in that neighbourhood. As regards the mortality of Manchester, Dr. Watts stated that the death-rate in the city had decreased in forty years from 44 per 1000 to 24 or 25 per 1000. He thought by the progress of the work of Board Schools and of Provident Dispensaries the mortality would go down still further. It is very gratifying to read such reports. We can only criticise them with a view to the production of still better ones. We should be glad to hear how much the dispensaries pay their medical men,—that is to say, the proportion between the work that has to be done by the medical officers and the remuneration they receive for doing it. Secondly, we shall not be considered ungracious in reminding the sanitary authorities that in the week ending Sept. 4th the mortality of Salford was at the rate of 35.1 per 1000, and that it shared with Leicester in that week the discredit of the highest mortality in England from the seven principal zymotic diseases. The extension of Provident Dispensaries would tend greatly to the reduction of this mortality, as would also the more extensive establishment of *crèches*, where infantile life might be considered and cared for in the unavoidable absence of the mother. We may direct attention to a letter signed "L.R.C.P. Ed." printed in another column, in which the writer defends the system of provident dispensaries.

THE MEDICAL SCHOOL AT SHEFFIELD.

AN anonymous writer, signing himself "Investigator," in a letter to the *Sheffield Daily Telegraph*, discusses the expediency of procuring a new site for the medical school at Sheffield. He strongly opposes the proposal, on the ground that any want of success in the medical school in this town arises not from any fault in the building, but from other causes. Amongst them he assigns a principal place to the fact that the teachers are too much occupied in the arduous work of practice to be able to give proper attention to teaching duties. He adduces the "comparatively small population of Sheffield," "the exceptionally small fees customary there," and entailing large and laborious practices, as reasons for doubting the desirability of perpetuating the Medical School. This writer may be correct, but some of his arguments are weak. The population of Edinburgh, with a medical school in the university only of 1200 students,

is less than that of Sheffield—196,979 against 239,346. Newcastle-on-Tyne, with a fair provincial school, has only 128,443. The population of Leeds only exceeds that of Sheffield by about ten thousand. There is population enough for the purpose of a good medical school. Whether there is anything in medical practice different from that which obtains in other similar towns is a different and an interesting question, in which the profession in Sheffield must be the best judges; but we should be sorry to think that the conditions of medical life amid nearly a quarter of a million of people are so hard and commercial as to leave no time for the work of medical education.

THE ACTION OF THE HEART.

THE differences in the action of the right and left ventricles of the heart have been studied by MM. Chauveau and Marey. The form of the intra-cardiac pressure is, they find, not the same in the two ventricles. The maximum of effort of the right ventricle is attained from the commencement of the systole, while in the left ventricle the pressure goes on increasing up to the end of the systolic period. The pulsation of the heart which reveals the changes in the consistence of the ventricles, varies with the variations in the pressure exerted on the blood in the interior. Accordingly different traces are obtained from the right and left side of the heart. M. Marey has endeavoured to ascertain a criterion to indicate which ventricle is furnishing a given tracing. He finds that the two sides of the heart do not behave in the same manner during an arrest of respiration. The stasis in the right side, due to the impeded pulmonary circulation, soon changes the character of the corresponding pulsation. It loses its amplitude and it becomes several times more feeble. The lessened amplitude is due to the elevation of the base line, the summits always presenting the same horizontal line. The tracings from the left side of the heart show, on the other hand, an increase of amplitude instead of a diminution. Another distinctive sign depends on the intimate connexion between the blood pressure in the left side of the heart and in the aorta. If an influence lowers the aortic arterial tension (as by nitrite of amyl) so as to cause conspicuous waves in the aorta, similar waves occur in the trace obtained from the left ventricle, as a bifurcation or trifurcation of the summit. The tracing from the right ventricle, however, only presents indications of those waves which arise by propagation.

SANITATION AT OBER-AMMERGAU.

THE passion plays at Ober-Ammergau have this year been successful beyond all hope. The number of visitors was so considerable that many deemed themselves fortunate in obtaining sleeping accommodation in haylofts. The receipts made by the villagers who take in lodgers and by the performers must have swollen the budget of the local authorities to gigantic proportions. Under such circumstances we may, in the name of the visitors whose presence has enriched this village beyond all parallel, protest that some small proportion of this wealth might be devoted to observance of the laws of health and of decency, which at present are but too often totally disregarded. A square box placed in the centre of an ordinary room, containing a leaky pail, even though ornamented by the rough wood-carving of an Ober-Ammergau artist, is not our ideal of commodious house-drainage. The pools of escaped liquid matter formed on the floor and saturating the basement of the houses are neither pleasant nor safe. The inhabitants also manifest a distinct disinclination to empty these obnoxious buckets, and when finally they are compelled to do so, the pail is rarely conveyed more than a few yards from the door of the house, so that the outer air as well as the

inner air is more or less poisoned by this reckless and disorderly disposal of sewage. The passion plays originated in an outbreak of what was called plague, though it was probably typhus fever. The malady was imported by a peasant who came to visit some relations, and it resulted in the death of eighty persons. This caused so great a panic that the superstitious inhabitants determined to institute a passion play, which was to be repeated every ten years if the plague ceased. As this took some trouble to organise, the plague had time to wear itself out before the performances were completed, and they have consequently been repeated every ten years. If, however, some sanitary measures are not adopted for the reception of the thousands of tourists who now flock from all parts of the world, and crowd together in this little village, epidemic disease will probably make its reappearance. The villagers have made their fortunes out of the first advent of the plague, but they should be careful, or a second epidemic may rob them of these advantages. The theatre, we are informed, is always full and it holds six thousand persons. The price of the places varies from one to twelve shillings; the working expenses are very small, and there are two performances per week. Surely the margin of profits will admit of some little expenditure in defence of public health, and in the cause of cleanliness, which is next to the godliness the pious villagers so loudly profess.

THE PHYSIOLOGY OF WALKING.

M. MAREY has applied the graphic method to the investigation of some points in the physiology of walking. Some time ago he devised an apparatus for registering the steps, which he has called an "odograph." It consists of a small cylinder, rotating by means of clockwork in its interior; and of a pen, which marks on the cylinder, and is raised at each step by an impulse communicated by a ball of air beneath the sole. Observations have been made on a number of young soldiers. It was ascertained that the step is longer in going up-hill than in going down-hill. It is shorter when a burden is carried; longer with low- than with high-heeled boots; longer when the sole is thick and prolonged a little beyond the foot, than when it is short and flexible. It thus appears that the heel may, with benefit, be almost indefinitely lowered, while it is disadvantageous to prolong the sole of the boot beyond a certain limit, or to give it an absolute rigidity. Some influences which lengthen the step lessen its frequency; so in going up-hill the step becomes at the same time longer and less frequent. In walking on level ground the length of the step and its frequency are always proportioned; the quicker the walk, the longer the step. M. Marey is inclined to believe that when the steps are lengthened by a change in the boot, the recurrence is rendered more frequent.

HOSPITAL DIETARIES.

AT the half-yearly meeting of the subscribers to the Bristol General Hospital, the chairman, Mr. Naish, submitted the usual report, in the course of which he stated that the medical staff were rather extravagant in their dietary arrangements. They ordered a great deal of fish and fowl, with consequent great increase in the expenditure. The Rev. Canon Girdlestone, in moving a vote of thanks to the chairman, whose devotion to the institution he warmly eulogised, ventured to differ from him upon the above point, and quoted from his experience of the poor that the change from their scanty living to the generous diet of the hospital materially aided in their recovery; and he would therefore leave the question of diet to the medical staff; in which the chairman concurred. No doubt it is in matters such as these that hospital expenditure is much increased; but we are pleased to see that there was no intention to tie the hands of

the medical staff, or to dictate to them as to the manner in which the patients should be dieted. This is a matter in which they only can judge, and they must consider the welfare of their patients before the question of hospital finance. Parsimony in this direction is, after all, the worst paying policy.

CADAVERIC ALKALOIDS.

THE properties of the alkaline compounds which are formed during the decomposition of animal tissues have been the subject of an investigation by MM. Brouardel and Boutmy, which has been communicated to the French Association for the Advancement of Science. Such substances have been called *ptomaines*, and they have been found in the bodies of individuals who have died a natural death, and also in those who have been poisoned. In cases in which the tissues are to be subjected to chemical analysis, it is important to prevent the formation of these alkaloids, and the most efficient agent for this purpose is cold, and hence M. Brouardel has arranged for bodies which are to be subjected to analysis to be kept in the Morgue in chambers of refrigerated air. The "*ptomaines*" come into the general class of organic alkaloids, and many of them are most energetic poisons, others being quite innocuous. Although there are many distinct substances in the class, identical bodies are formed under very different conditions of putrefaction. The same alkaloid, for instance, was found in two individuals who were poisoned, the one by carbonic oxide, the other by prussic acid. A few are fixed, but the majority are volatile. A substance closely analogous to veratrine was found in a body which had been eighteen months in the Seine, and another in a goose which had been subjected to the heat necessary for cooking. Certain of these substances are clearly poisonous to man, and apparently cause the toxic effects which occasionally result from eating decomposing meat. Symptoms of serious poisoning occurred, for instance, in twelve persons who had partaken of a putrid goose which had contained a peculiar alkaloid, and one of these persons died in a few hours after nausea and vomiting. These poisonous substances may be quickly formed, for in this case the goose had been purchased in the market in the morning of the day on which it was eaten.

THE SANITARY CONGRESS.

THE annual autumnal Congress of the Sanitary Institute commenced its sittings, under the Presidency of Earl Fortescue, in Exeter on Tuesday, the former part of which day was devoted to the usual procession, festivity, and mutual congratulations. On Wednesday, Professor de Chaumont presided over the section of Sanitary Science and Preventive Medicine, and delivered an interesting address. Mr. H. C. Burdett then read a paper on the "Unhealthiness of Public Institutions," which excited a long and animated discussion, many leading sanitarians taking part in it.

THE SENSE OF COLOURS.

M. CHARPENTIER of Nancy has propounded to the French Association for the Advancement of Science the somewhat novel theory that the sense of light and that of colours is independent. White light being the sum of the various colours, it has been commonly thought that the sensation of white light was simply the sum total of the sensations of its constituent colours. On the ground that the sensitiveness of the eye for white light may be increased—as, for instance, by the previous absence of all light—without the sensitiveness for colour being increased, he urges that there is a colour-sense as distinct from that of light as is the sense of touch from the sense of heat.

THE VAUXHALL RAILWAY ACCIDENT.

ON Friday last Watson, the driver of the stationary engine in the recent accident at Vauxhall, was seriously ill with new symptoms, accompanied by a high temperature (104° to 105°). Mr. Sydney Jones then saw him in consultation with Dr. Crossman. It was decided to trephine Watson for a punctured wound of skull; a piece of the outer table of the right parietal bone had been driven in, splintering and depressing the inner table. The man has since been improving. On Saturday, the day after the trephining, his temperature had fallen to 101° ; on Monday to 99.6° .

ICHTHYOSIS.

MARKED changes in the nerve-roots in congenital ichthyosis have been found by M. Leloir. The cutaneous nerves presented changes such as have been before described. In the nerve-roots, moreover, at their origin from the spinal cord, a considerable number of nerve-fibres, of both the anterior and the posterior roots, were degenerated; presenting the lesions of "atrophic neuritis," empty sheaths with nuclei here and there, the myelin and axis cylinder having completely disappeared. A few nerve-tubules presented more recent lesions. The spinal ganglia were not examined.

THE death is announced of Mr. W. B. Whitmarsh, Coroner for Wilts. Mr. Whitmarsh, at the time of his decease, was the oldest coroner, both as to age and office, in England, he having held the post for fifty-three years. The county coronership had descended from father to son for more than three hundred years, all, with the exception of its latest holder, having, we believe, belonged to the medical profession. Dr. Michael Whitmarsh, son of the deceased, will, it is understood, solicit the suffrages of the freeholders for the post.

MR. R. BASIL CANE, Local Government Board inspector, has been conferring with the West Derby Guardians on the subject of boarding-out of pauper children. Whilst generally approving of the system, Mr. Cane submitted a few suggestions for its improvement, and amongst other pieces of useful advice, pointed out the necessity of the children undergoing a medical examination before being dismissed from the workhouse.

DR. AUSTIN FLINT, JUN., has been invited to the Chair of Physiology in the Jefferson Medical College, Philadelphia, but has declined, preferring to remain at Bellevue Hospital Medical College, New York. We congratulate Bellevue on this decision of Dr. Flint, who must be regarded as not only one of the most advanced teachers in the States, but one of the best friends of higher medical education.

THE work of Dr. W. W. Ireland, of the Scottish National Institution at Larbert, on Idiocy and Imbecility has recently been translated into the Russian language by Dr. Tomaszewski, with a preface by Professor Mierzejewski; at the same time the Medico-Psychological Society of St. Petersburg (Société des Psychiatres) has conferred on Dr. Ireland the diploma of Corresponding Member of their body.

THE Melbourne Hospital Committee (says the *Australian Medical Journal*) has determined to pay the whole of Dr. Stirling's expenses in the recent action of Dean v. Stirling, notwithstanding the recommendation of a sub-committee that one-half only should be paid.

WE regret to report the death, from heat apoplexy on August 13th, at Sibi, en route to Kandahar, of Surgeon-Major John Simpson, in medical charge of the 23rd Bombay Native Infantry. Dr. Simpson was in his thirty-ninth year.

ABOUT £88,000 has now been subscribed towards the cost of the projected University College of Liverpool. Amongst the endowments is a sum of £10,000, given by the trustees of the late Mr. Roger Lyon Jones to the Royal Infirmary School of Medicine, to found a chair of Experimental Physics, with which Mathematics will for a time be associated.

THE Committee of the Manchester Free Library have resolved to place at the disposal of the Guardians books which have been withdrawn from circulation as worn out or imperfect, and also a number of newspapers, for the use of the inmates of the workhouse hospital. This is a work of practical benevolence which we have long advocated.

WE regret to notice the death of another army medical officer in the terrible catastrophe at Naini Tal. Surgeon-Major J. B. Hannah, M.D., is reported in the meagre telegram from India to be among the killed. Further particulars of this untoward occurrence will be anxiously looked for.

IN the late sortie from Kandahar against Ayoo Khan's forces Dr. Trafford was wounded, but is reported to be doing well.

DR. T. SPENCER COBBOLD, F.R.S., has been elected Foreign Corresponding Member of the Turin Royal Academy of Agriculture.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Huddersfield (estimated population 80,245).—Dr. Spottiswoode Cameron's report for the year 1879 has a special interest from the information it contains, particularly during a considerable prevalence of scarlet fever, respecting the operation of the compulsory clauses regarding the notification of infectious diseases contained in the Local Improvement Act for the borough. He tells us that this clause "has been more carefully attended to than formerly," but that there is, in this respect, still much to be desired. 244 cases of infectious disease were, it appears, reported to the corporation under the clause. Of these cases 175 were removed to the corporation's fever hospital, of whom 12 died; and 69 were isolated at home, of whom 16 died. In addition to information of cases received under the compulsory clause, the corporation obtained information from other sources of 217 cases of infectious diseases, including 43 first ascertained from the death returns. Three of these cases were removed to hospital, of whom 2 died; and 101 were isolated at home, "or were supposed to be," of whom 27 died. It would thus appear that of 461 cases, little more than half were brought to the knowledge of the sanitary authority by the operation of the compulsory notification clause. Obviously there is much friction (passive if not active) still to be overcome in Huddersfield before the population can reap the full benefit of the clause.

"There are two difficulties," Dr. Cameron observes, "in the working of our present clause. One is the 'sufficient accommodation' proviso. Should the new Act become law information will be required in every case of certain infectious diseases, and the shifting of the responsibility of determining what is sufficient accommodation from the medical attendant to us will place him in a less embarrassing position with the friends of the patient. The other difficulty is one of diagnosis. It is often quite impossible to say whether a particular disease really exists or not. Scarlet fever not unfrequently presents itself without a rash, with no noteworthy fever, and without any very marked indication of sore throat. Such cases are apt to be overlooked; it is such

cases often that spread the disease to a whole family, and, unfortunately, parents have too frequently the notion that these cases are not infectious, or that infectiousness ceases when the children can run about. Several instances of this kind have come under our notice during the past year, and in many of them there seems every reason to believe that the parents, and sometimes even the doctor, have been in doubt as to the real nature of the malady. Such cases, too, present a grave difficulty to your medical officer, for if brought under his notice it is a serious responsibility to remove such doubtful cases to hospital; while, if not removed, they may cause grave mischief in their neighbourhood. We have had very little opposition to contend with in carrying out the clause. As has been already hinted, our difficulty at one time was rather to find accommodation for the patients."

The hospital accommodation at the command of the corporation was inadequate for the number of cases which might have been isolated, alike to the advantage of the community and the patient. The actual accommodation afforded by the hospital is not stated, but there were 22 patients in it on the 1st January, 1879, and 200 cases were treated in it in the course of the year. Of these cases 175 were cases of scarlet fever, 17 of enteric fever, 1 of diphtheria, 4 of measles, and 3 of a doubtful nature. The hospital accommodation is being increased by the erection of a new pavilion, stated to be, at the time of completion of this report, "far advanced towards completion."

South Shields (estimated population 62,000).—Mr. John Spears reports for the year 1879 a birth-rate of 35·8 per 1000 population, and a death-rate of 19·6—"the lowest death-rate for South Shields on record." The most noteworthy facts recorded in the report related to an epidemic of scarlet fever which had been prevalent in the borough for two years, but which in 1879 began to give indications of decline. The measures which it had been practicable to put in operation with a view of preventing this epidemic proved to be inadequate from the absence of proper hospital accommodation for the isolation of sufferers, and of the necessary statutory provisions for the enforcement of such isolation at their own houses. Four hundred cases of the disease were brought to the knowledge of the medical officer of health, and in each case disinfectants were distributed free of cost, and disinfection made use of under the supervision of the medical officer of health or the inspector of nuisances. At the time of the first outbreak of the disease, the influence of public day-schools in the dissemination of the infection was very apparent; and the same fact was made further so as the disease extended. On different occasions children were found attending school from infected houses, and local outbreaks of the disease were clearly traceable to conveyance of the infection in this manner. The extension of the disease, moreover, was observed in tenemented houses by its spread, in several instances, from the families on the lower floor to the families on the higher floors. The congregation of neighbours in fever-stricken houses for purposes of sympathy and gossip proved also to be a fertile source of mischief. "To deal effectually with such an outbreak as that from which we have suffered and are suffering," Mr. Spears observes, "suitable hospital accommodation for the removal of the afflicted from tenemented houses is required, and also a system of compulsory registration of infectious diseases, with increased statutory powers to prevent the exposure of reckless and ignorant persons, themselves and their children, to the dangers of infection."

Mr. Spears relates the following instances of recurrences of zymotic disease in a particular house, occupied by two tenants. In this house, within twenty months, there had been three separate outbreaks of diphtheria, all fatal; one of scarlet fever; and two of erysipelas. An examination of the house had been made, but no sanitary defects discovered. On a further examination, however, being instituted, it was found that the rain-spouts from the roof at the front of the building ran through the house, quite out of sight, to a rain-water tank in the back yard. This tank had an overflow-pipe communicating directly with the sewer; and it was found by experiment with sulphuretted hydrogen gas that sewer-air could, from the escape-pipe of the tank, reach every room in the house.

Five cases of typhus occurred in the borough during the year, all caused by infection introduced from Jarrow, where the disease had prevailed.

Whitechapel.—Mr. John Liddle's report for the second quarter of the present year (ending July 3rd) shows a mor-

tality at the unusually low annual rate of 19·8 per 1000 population of the district. The number of deaths during the last quarter was less than had occurred in any other quarter since the establishment of the local Board of Works. An effort made by Mr. Liddle and his board to induce the Metropolitan Board of Works to adopt, under the Artisans and Labourers' Dwellings Act, 1875, an improvement scheme in part of the Whitechapel district failed, the Metropolitan Board holding that the unhealthy area, to wit, 8650 square yards (or nearly two acres), and containing a population of about 1050 people, was too small to admit of a comprehensive improvement scheme being designed. The reason assigned for not dealing with the area seems curious in view of the public-health aspects of the question. Mr. Liddle expresses his regret that attempts should have been made to alter the existing Vaccination Acts, so far as repeated prosecutions of persons who refuse to have their children vaccinated are concerned. He believes that such alteration would have seriously interfered with the successful way in which the Acts are now being worked within his district, and he deprecates meddling with them.

It is pleasant to read that a disused Quakers' burial-ground in Whitechapel has been converted into a public recreation ground. The ground contains 5445 square yards, or about 1½th acre, and it has been laid out by Mr. Irons and ornamented with shrubs and flowers. It was opened for public use by the Prince and Princess of Wales on June 24th, and it now forms, Mr. Liddle says, "an enjoyable playground, where children can amuse themselves in safety, and where adults may find temporary rest and repose away from the confined and crowded courts in which so many of the poorer inhabitants of this district reside." Mr. Liddle tells us that there are still two other open spaces in Whitechapel—both disused burial-grounds—which may be made available for public recreation-grounds, and we heartily sympathise with his hope that they may shortly be converted to this use.

THE DISTRESS ON THE WEST COAST OF IRELAND.

One of the most interesting official papers which have been issued with respect to the distress in Ireland is a report by Captain Geo. Digby Morant, R.N., on the operations of the several vessels of the Royal Navy, six in number, which, under the command of H.R.H. the Duke of Edinburgh, were directed to aid in the distribution of relief to the distressed populations on the West Coast of Ireland and on the islands there. The service of these vessels, forming what is known as the "Relief Squadron," began early in the year, and continued to the 1st of August; and during this period they carried large amounts of food and clothing from the Mansion House and Duchess of Marlborough's committees to places which would else have been inaccessible, or with difficulty accessible, and so obviated, in all probability, much fatal starvation. The communities relieved are estimated approximately to number 36,841 persons, and the relief issued consisted of 856½ tons of meal, 453 tons of seed potatoes, 30 tons of oats and barley, and 110 bales of clothing, besides a considerable quantity of loose clothing. The report throws a good deal of light upon the present condition of the populations relieved. The distress did not come suddenly upon them on account of the failure of last year's harvest. For several years the people have been getting poorer and poorer, when all credit having been stopped by the shopkeepers, and the potatoes saved from the previous harvest eaten, the crisis was determined, and the people reduced to the verge of starvation. Kelp-burning, which not long ago formed the principal source of livelihood of the people, has seriously fallen off in value of late years. In Tory island, for example, where not long ago the burnt kelp sold for £7 a ton, the material only realised £2 a ton last summer. Again, in Connemara, in the Kilkieran district, up to four or five years ago a sum of £15,000 a year was paid for kelp, but during the last two or three years the district has received only £2000 or £3000 a year. While the times were prosperous the population appears to have multiplied largely, the early age at which marriage takes place—namely, nineteen and twenty years—contributing greatly to this increase. The kelp industry having failed, the people had to fall back chiefly upon tilling the ground and fishing. But the crops capable of being grown are utterly insufficient to support the populations, and, moreover, the holdings are very small; while the means for fishing are, as a rule, too imperfect to help much in the sustenance of the communities. It is the old distressful story of a people too thick upon a

ground where there is no dependable industry for support—where the land itself, partly from the nature of the climate, partly from the smallness of the holdings, cannot support them as they ought to be supported, and where there is not the means of developing new sources of profitable industry. Life is, as a rule, only maintained on the cheapest and most accessible food, at the best in barely sufficient quantity; and a succession of imperfect crops, or a failure of the principal crops, at once plunges the mass of the population into an extremity of destitution.

THE METROPOLITAN WATER-SUPPLY.

The Metropolitan Asylums Board, at their meeting on the 18th inst., had under consideration the occasional failure of the water-supply, derived from the Southwark and Vauxhall Company, of the Stockwell Fever Asylum. Notwithstanding the intervention of the Local Government Board, who directed an inquiry into the matter, the explanation given by the Company appears to have been most unsatisfactory. The serious consequences apt to arise from a great hospital being deprived, even for a very brief time, of its water-supply, at once arrests the attention. But proportionately the evil is no greater than when a like fate befalls a private dwelling, whether by accident or by the cutting off the supply by the Company. Accidental failures cannot at all times be guarded against, but there needs to be some control, in the sanitary interests of the public, over the power which the water companies now hold of depriving houses of their water-supply. In the impending revision of the powers, if not entire change in the position, of these companies, regard should be given to this absolute control over the supply, so that it be not exercised to the prejudice of the public health.

THE METROPOLITAN INFECTIOUS-DISEASE REMOVAL MUDDLE.

At the meeting of the Metropolitan Asylums Board just referred to an interesting illustration of the confusion existing in London regarding the removal of cases of infectious diseases to hospital for purposes of isolation was afforded. A patient suffering from scarlet fever had been sent from University College Hospital to one of the Asylums Board hospitals without regard to the required forms. If a pauper, the patient should have been sent through the agency of the relieving officer; if a non-pauper, through the proper officers of the Vestry. It is to be inferred, however, that the Vestry have not made any arrangement under the Poor-law Amendment Act of 1879 for the admission of non-pauper cases to the asylum hospitals. The Vestry concerned have, in fact, evaded their responsibilities in this respect, and the Local Government hold that the Asylums Board are not justified in receiving patients who are not paupers. The Poor-law Amendment Act of 1879, so far as relates to facilitating the admission of non-pauper patients to the Asylums Board hospitals, has proved a failure, and the question of hospital isolation of cases of infectious diseases in its general public-health aspects, and not as a poor-law matter only, has still to be solved. Is it hopeless to look for a statesman with capacity and courage sufficient to relieve the metropolis from this discreditable administrative muddle?

QUEENSTOWN WATER-SUPPLY.

Recently the engineering inspector of the Local Government Board for Ireland held an inquiry at the Town-hall, Queenstown, as to the present supply of water to this town. Evidence was given as to the inadequate supply by various witnesses. Dr. R. Townsend, one of the dispensary medical officers, stated that in the district of which he had charge there was but one well available, and one public fountain from which water could be obtained only for a short period every day. The town commissioners have applied to the Local Government Board to carry out a scheme for improving the water-supply, as they believe that the water company is unable to meet the wants of the inhabitants.

COTTAGE HOSPITALS.

Dr. Paget Blake, R.N., recently brought before the Plympton St. Mary Board of Guardians (whether sitting as guardians or as the rural sanitary authority does not appear) the question of establishing a cottage hospital for the isolation of cases of infectious diseases in each district of the union. He advanced most excellent arguments in

favour of this being done, but the guardians appeared to have so hazy a knowledge of their respective duties in the matter under the poor-law and the public-health law, and of the mode of reconciling their responsibilities under the two series of laws, that the discussion proved abortive. From the remarks made by the clerk, in the progress of the meeting, it would appear that the Local Government Board has not been unmindful of the wants of the district in respect to hospital accommodation for cases of infectious diseases, and has intimated that such accommodation must, when provided, be kept entirely apart from the workhouse.

BOURNEMOUTH.

We congratulate the Bournemouth Commissioners on the step they have taken for making all who are concerned in their district familiar with their newly adopted regulations relating to house-drains in communication with the public sewers. These regulations are founded upon the model bye-laws of the Local Government Board, and they have been printed for circulation, accompanied with drawings illustrative of the mode of carrying out in detail the regulations. The drawings are clear, readily comprehensible, and serve admirably to show the thoroughly sound principles upon which the regulations have been formed. We trust that the good example set by Bournemouth in this respect will be followed by other health resorts.

SUBURBAN DWELLINGS.

We are glad to learn that the Edmonton Local Board have instituted proceedings against, and successfully prosecuted, a builder for using as mortar a compound chiefly consisting of common mould in the construction of houses. We welcome any indications of activity on the part of local authorities in the suburbs in endeavouring to grapple with the serious sanitary evils attaching to much of the building operations going on there, and which, we believe, are in no place to be found more glaring than in Edmonton.

THE ADULTERATION OF MILK.

The numerous instances recorded in the public press of prosecutions by sanitary authorities for milk adulteration lead to the conclusion that such adulteration must prove a very profitable process. An instance recently occurred in Manchester, where a milk-dealer was charged for the eighth time with adulterating milk, or for offences connected therewith. He was fined £20, and it appears that the total fines he had paid for the offence, including the fine last inflicted, amounted to £110, irrespective of the costs of the prosecutions.

On the 3rd instant Mr. Alderman Bennett, of Liverpool, had presented to him by Viscount Sandon, M.P., in the name of numerous friends, a testimonial and address in recognition of his municipal services, and as token of the esteem in which they held him. Our readers will learn with surprise that among the "services" Mr. Bennett was deemed to have rendered to the borough, was his strenuous support to the project of supplying Liverpool with water obtained locally from the red sandstone;—in other words, from wells within the limits of the borough, as against the Rivington Pike scheme; and his opposition to the introduction of water-closets in the smaller classes of property; referring, we presume, to the introduction of the trough water-closet which is understood to have worked so admirably, and which is known as the "Liverpool trough-closet."

A Fulham pauper, an inmate of the workhouse there, has complained to the Local Government Board, in respect to the diet he receives, as follows: "We get hot water without any sugar in; and on pudding days we get no suet in the pudding, and not half done, it is like putty soup; and stew days we get some smashed bones, and not any herbs in it, only a few old onion-stalks, and that is very seldom. I only get meat once a week, and when I get it I cannot eat it, and we do not get weight. . . . The food is not properly cooked at all."

At Barmouth (Merionethshire) bathing appears to be permitted in primitive guise and in friendly association, male and female; and so attached is the so-called sanitary authority to the locally produced filth, that it proposes to turn the sewage of the place into the harbour, so that visitors may not suffer by being subjected to too sudden a change in passing from the filthy air of the town to the purer air of the sea-shore.

The autumnal outbreak of letters to *The Times* on the water-supply of rural districts and water-supply generally, although briefer than customary, has not been useless. It is rare for a correspondent not to state some fact or express some opinion worthy of consideration. The instructional aspect of this correspondence, which we are now fairly justified in looking for annually, cannot well be overrated.

Dr. Kelly, medical officer of health for the West Sussex combined district, has recently submitted to the Horsham Rural Sanitary Authority a report showing excessive pollution of the river Arun, owing to the defective outfall of the new sewage farm of the urban sanitary district of Horsham. The stream below the outfall is described as a black, thick, unbearably offensive fluid.

A correspondent of the *Daily Telegraph*, writing to that journal on drainage and health, makes the following pithy statement:—"My experience of country places points to the blunt truth of a remark I once heard, 'A man buys a plot of land, builds a house, and digs two holes; out of the one he drinks, and into the other he casts all manner of dirt and refuse.'"

The *Cambrian News* is righteously wrathful with the combination of physical and moral filth to be found in Aberystwith, and takes the local authority soundly to task for its neglect in this matter.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

THE recent decline of temperature caused a slight decline of urban mortality last week. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 4814 births and 3591 deaths were registered last week. The births were 371 below, whereas the deaths exceeded by 316 the average weekly numbers during 1879. The deaths were 52 fewer than those returned in the previous week, and were equal to an annual rate of 25.0 per 1000 against 24.6 and 25.4 in the two preceding weeks. The lowest death-rates in the twenty towns last week were 16.7 in Plymouth, 20.0 in Bristol, 20.5 in London, and 25.7 in Portsmouth. The rates in the other towns ranged upwards to 34.3 in Liverpool, 35.6 in Hull, 35.9 in Norwich, and 36.5 in Leicester. The high rates in these last-mentioned towns were mainly due to excessive zymotic fatality. During the eleven weeks ending last Saturday, the death-rate in these twenty towns averaged 23.3 per 1000, against 24.3 and 18.2 in the corresponding periods of 1878 and 1879.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 1120 and 1190 in the two preceding weeks, declined to 1009 last week. Of these 818 resulted from diarrhoea, 94 from scarlet fever, 59 from whooping-cough, and 58 from fever, principally enteric. The annual death-rate from these seven diseases averaged 7.4 per 1000 in the twenty towns; it was but 3.9 and 4.2 in Brighton and Plymouth, while it ranged upwards in the other towns to 17.3 in Leicester, 17.4 in Hull, and 18.8 in Norwich. Scarlet fever showed the largest proportional fatality in Sunderland, and enteric fever in Sunderland and Portsmouth. The 18 deaths from diphtheria included 12 in London and 2 in Manchester. Diarrhoea fatality was somewhat lower than in the previous week; the annual death-rate from this disease averaged 8.2 per 1000 in the nineteen provincial towns, while in London the rate was but 3.1. Among the nineteen towns, the diarrhoea death-rate ranged from 3.4 and 3.5 in Brighton and Plymouth to 15.3 in Leicester, 15.7 in Hull, and 15.8 in Norwich. Small-pox caused 3 more deaths in London. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily declined from 200 to 104 in the eight preceding weeks, rose to 116 on Saturday last, and 27 new cases of small-pox were admitted to these hospitals during the week, against but 7 and 13 in the two previous weeks. The Highgate Small-pox Hospital contained 9 patients on Saturday last.

The deaths referred to diseases of the respiratory organs in London, which had been 152 and 124 in the two preceding weeks, rose again to 153 last week, although they were still 6 below the corrected weekly average; 91 resulted from bronchitis, and 45 from pneumonia. The annual death-rate

from lung-diseases was equal to 2·2 per 1000 in London, against 4·6 in Liverpool, and 3·4 in Salford.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 20·3 per 1000, against 19·3 and 18·2 in the two preceding weeks; this rate was 4·7 per 1000 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 14·4 and 16·9 in Dundee and Leith, to 25·6 and 39·0 in Greenock and Perth. The fatal cases of the seven principal zymotic diseases in the eight towns were 163, against 130 and 129 in the two preceding weeks; they included 69 from diarrhoea, 36 from scarlet fever, 23 from whooping-cough, 17 from fever, principally enteric, 12 from diphtheria, 6 from measles, and not one from small-pox. The annual death-rate from these seven diseases averaged 6·6 per 1000 in the eight towns, which, although showing an increase upon the zymotic rate in recent weeks, was 1·8 per 1000 below the rate from the same diseases last week in the large English towns. The excess in the English zymotic death-rate was entirely due to the greater fatality of infantile diarrhoea. The zymotic death-rate in the Scotch towns last week ranged from 3·6 and 4·2 in Leith and Paisley to 7·8 and 8·1 in Perth and Edinburgh; the excess in the zymotic rate was due to diarrhoea in Perth and to scarlet fever in Edinburgh. The fatal cases of diarrhoea in the eight towns, which had been 65 and 63 in the two previous weeks, were 69 last week, and equal to an annual rate of but 2·8 per 1000, while in the twenty English towns the diarrhoea death-rate averaged no less than 5·7. The largest proportional fatality from diarrhoea in the Scotch towns occurred in Perth and Aberdeen. The 17 deaths referred to fever showed a further increase upon recent weekly numbers, and included 10 in Glasgow and 2 each in Edinburgh, Dundee, and Aberdeen. Fever fatality last week was greater by 73 per cent. in the Scotch than in the English towns. Scarlet fever also showed an increased fatality in the Scotch towns last week, causing 36 deaths against 22 and 18 in the two previous weeks; 15 occurred in Edinburgh (against 8 in the previous week) and 12 in Glasgow. Seven of the 12 deaths from diphtheria occurred in Glasgow, and 2 both in Edinburgh and Greenock. The deaths attributed to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) were 61 last week in the eight towns, against 65 and 60 in the two preceding weeks; the annual death-rate from these diseases was equal to 2·5 per 1000, against 2·0 in London.

HEALTH OF DUBLIN.

The excessive death-rate in Dublin showed a considerable increase last week. The annual death-rate in the city, which had been equal to 35·5 and 34·7 in the two preceding weeks, rose last week to 39·3, a higher rate than has prevailed in any week since the beginning of June. During the past eleven weeks of the current quarter, the death-rate in the city has averaged no less than 34·1 per 1000, against 21·5 in London and in Edinburgh. The 237 deaths in Dublin last week included 78, or nearly 33 per cent., which were referred to the seven principal zymotic diseases, exceeding the number of these deaths in any previous week of the year; 38 resulted from diarrhoea, 12 from whooping-cough, 10 from measles, 9 from scarlet fever, 7 from fever, and one each from small-pox and diphtheria. The annual death-rate from these seven diseases was equal to 12·9 per 1000 in Dublin, while it did not exceed 4·7 in London, and 8·1 in Edinburgh. The 38 fatal cases of diarrhoea in Dublin exceeded the number returned in any week for this year, and were equal to an annual rate of 6·3 per 1000; the diarrhoea death-rate in London did not exceed 3·0 per 1000. The deaths from measles and whooping-cough showed a marked increase in Dublin last week; while those from scarlet fever and enteric fever differed but slightly from those returned in the previous week. The rate of infant mortality showed a considerable decline in Dublin last week.

SUICIDES IN LONDON.

The Registrar-General's returns show an unusual excess in the recent recorded cases of suicide in London. During the three weeks ending last Saturday no less than 38 cases of suicide were registered in the metropolis, whereas the

average number in the corresponding period of the ten years 1870-79, after correction for increase of population, is but 17. The London suicides in the past three weeks have, therefore, been more than twice the average number. Eleven suicides were effected by drowning, 9 by cut or stab, 8 by poison, 6 by hanging, only one by gunshot, and in three other cases the mode of suicide was indefinitely described. No record of assigned causes of suicide is attempted, but even if it were very little assistance would be rendered in the way of ascertaining the true cause of the recent increase of suicides in London.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE LONDON FOG OF NOVEMBER, 1879, TO FEBRUARY, 1880.

In a paper of very considerable interest, published in the recently-issued quarterly part of the *Journal of the Scottish Meteorological Society* (vol. v., pts. 49-53), Dr. Arthur Mitchell has endeavoured to show the influence on the death-rate of London of the very remarkable period of fog which occurred in the metropolis from November, 1879, to the first week of February, 1880. He writes of the fogs of this period as forming, in fact, one continuous fog, "constituting one of the most remarkable fogs on record in this country." From an analysis of the Registrar's Weekly Returns during this period he arrives at the following general results:—

(1) The whole death-rate was enormously increased. (2) No approach to so large an increase of the death-rate showed itself in any of the other British large towns for which we have weekly returns; and in connexion with this it is to be remarked that in none of them did fog of a noteworthy character occur. (3) Asthma is the disease which appeared to be most directly influenced in its fatality by the fog. In the first three weeks of 1880, when the fog more or less completely disappeared, the deaths from this disease fell at once to about 30 per cent. below the average, having previously risen in the middle of December, when the fog was severe, to 43 per cent. above the average, and rising again in the end of January and beginning of February, when the fog was densest and most persistent, to 220 per cent. above the average. When the fog finally disappeared, as it did after the end of the first week of February, the deaths fell to 40 per cent. below the average for the latter half of the month. (4) The deaths from bronchitis, pneumonia, pleurisy, and other lung diseases were greatly influenced in their number by the fog, but did not show the close and direct obedience to the varying density and persistence of the fog which the deaths from asthma showed. (5) In the case of whooping-cough, as was to a certain extent true of bronchitis, the pernicious effects of the fog continued to manifest themselves in an increased mortality during the whole period, and did not disappear, as in the case of asthma, during the temporary abatements of the fog. (6) The deaths from rheumatism did not show any clear relation to the fog, and the same thing can be said of the deaths from croup. (7) Other causes of death showed no very striking relation to the varying density and persistence of the periods of fog.

PELLAGRA.

A correspondent of the *Pall Mall Gazette*, writing from Venice, under the date of Sept. 1st, gives some interesting information about the prevalence of pellagra in the Lombardo-Venetian provinces. The number of pellagrosi in these provinces is estimated at no less than 100,000, and even this number is held by "one of the most practical writers on economical and social questions" as falling short of the reality. He describes briefly the state of the pellagrosi in the Santo Clemente Asylum at Venice, of which 500 of the 1000 beds it contains are occupied by sufferers from the disease. The malady is attributed to bad and insufficient nourishment, and particularly to an exclusive use of maize, especially of spoiled maize. The Mantua Commission on the subject suggest the formation of a committee in every commune, consisting of the syndic, a doctor, the president of the Congregation of Charity, and one agriculturist. The duties of this committee would be to supply all who were threatened by pellagra with proper food and medical care in their own homes or in a poorhouse; to open a bank of credit to assist the small peasant proprietors, small farmers, and day labourers; to transmit to the provincial deputation a

monthly report; and so forth. Upon this suggestion the *Pall Mall* correspondent observes: "Now, had these proposals been made to ward off cholera, small-pox, or any other contagious disease, they would at once have been accepted; but for a disease proceeding from misery, only affecting the poorest classes, never even menacing the well-to-do members of society, the very idea was scouted as anarchical. Hence pellagra flourishes and increases in the north of Italy, as do the Camorra, brigandage, and the Mafia in the south."

THE MASSACHUSETTS STATE BOARD OF HEALTH.

We should regard with profound regret the last (the eleventh) report of the State Board of Health of Massachusetts, now lying before us, if we did not feel assured that the Board had simply undergone a transformation, and that in the first annual report of the State Board of Health, Lunacy, and Charity of Massachusetts, it reappears in another, and, we presume, more influential form. The cessation of the reports of the former State Board would have been regarded as a serious loss to the literature of public hygiene, if it were not (as we are wishful to believe) that the new Board will no doubt continue to report in the same fashion, and, as we hope, with wider opportunities of enriching public-health literature. The eleventh report of the State Board, which relates to the six months ending June 30th, 1879, announces the transformation of the Board, and contains a report of certain cases illustrative of the law relating to noxious and offensive trades, and a series of instructive circulars issued by the Board on disinfection, care of young children, house drainage, &c. But the main bulk of the report is occupied by an index to the complete series. The first annual report of the existing Board is devoted to a description of the organisation of the Board, its several duties in relation to public health, lunacy, and pauperism, the laws under which it acts, and sundry papers relating thereto. The report is of considerable interest with reference to these matters.

THE WATER-SUPPLY OF LIMERICK.

The Corporation have under their consideration several schemes for a proper supply of water to this town, which at present is inadequate as regards quantity, while the quality is very inferior. The schemes are ten in number, and the estimate for the lowest will require an outlay of about £46,000. One plan proposes to bring the water from the river Clare, distant a dozen miles; another from the Mulkear river, flowing by gravitation to the local reservoir. A third suggests the Shannon, and to pump the water by steam-power into the service reservoir; while Doonas Falls, Castleconnel, and Lough Gur are other sources proposed for a water-supply. It will thus be seen that two methods are suggested—viz., by pumping and gravitation; but it is believed that the former method will be more suitable, more especially if the supply is obtained from the river Shannon. The Corporation will meet this week to decide on the course they will adopt in reference to the plans proposed.

Two cases of typhoid fever—one affecting a prisoner, the other a gaoler—are reported under somewhat anomalous circumstances in connexion with the Wormwood Scrubs prison. The prisoner died, and in the course of the inquest held on the cause of death it was stated that the prison was much exposed to nuisance from piggeries in the neighbourhood. The cases will, no doubt, be made the subject of official medical inquiry.

At the recent Trades' Union Congress, held in Dublin, the question of "woolsorters' disease" was discussed, and a resolution adopted, by a large majority, that the Parliamentary Committee of the Union be requested to continue their exertions with a view of obtaining protection for woolsorters against blood-poisoning (septic, that is) whilst following their occupations.

Sir Henry A. Hunt, C.B., has made his final award in respect of property to be taken compulsorily in Wolverhampton under the Artisans' Dwellings Act. The scheme provides for the outlay of £250,000 in making improvements in the centre of the town. The total value of the property arbitrated upon amounts to about £60,000.

A very fatal epizootic is reported among the crayfish in Bavaria.

MANCHESTER "SLUMS" AND AIR.

THE Manchester correspondent of *The Times* has been endeavouring to elucidate in the columns of that journal several of the great local questions, touching social matters, which at the present time are occupying the attention of the citizens of our northern metropolis. He has concerned himself particularly with the subjects of the housing of the labouring classes in the city, and with its air in relation to out-door exercise and to art. As regards "art," and the contending views of the Manchester folk and their Corporation with reference to the best methods for its greater development in the city, and how these views may be affected by the ordinary constitution of the city's air, these do not concern us here; and as regards the provision of facilities for out-door exercise and open-air recreation, this is an obvious need, and the Corporation would appear to have not been wholly unmindful of the requirements of the population in this respect. Nothing is said of the prospect of purging to a greater extent than has yet been done Manchester air of the dense volumes of smoke which from Monday morning to Saturday noon intermingle with the atmosphere, too generally reducing daylight to a dismal sort of twilight. The question of the slums has perhaps the most immediate interest for the medico-sanitarian and student of public health. It is well known that the Corporation of Manchester has been for some time depending upon the ordinary changes in progress within the city for the relief of those conditions attaching to the older parts of it most inimical to the health of its inhabitants. As the central parts have become more and more devoted to business purposes, the inhabitants have been displaced, and have moved to the outer and less thickly populated parts of the borough. The older, unwholesomely constructed and arranged cottages vacated have been cleared away to give place to warehouses and public buildings, and the displaced inhabitants have found house-room in the more open districts, where they are scattered comparatively widely over the ground, and are housed in dwellings constructed with a stricter regard to health principles. This migration to the outer districts has been largely assisted by a corresponding transference of manufactories to the same districts, rendering it in a measure necessary that the workpeople engaged in them should follow and establish their residences near at hand. The changes here noted have been proceeding so steadily of late years, and at so considerable a rate, that if we understand the question aright, the Corporation, under the advice of the medical officer of health, Mr. John Leigh, have determined not to interfere, but suffer them to proceed without interruption, and leave the present many defective conditions of cottage dwellings in central Manchester to be done away with, as they must be in a comparatively short time, by the natural operation of the business and social changes going on in the city. In so doing, it is argued the desired changes will be, as it were, insensibly effected, and with less difficulty to the displaced population, less danger of contingencies, such as dangerous overcrowdings of already occupied dwellings in the process of displacement, and greater certainty that the change would be made in such a way as would contribute best, from the public-health point of view, to the permanent well-being of the population. Of the soundness of the view here taken, assuming the facts to be as stated (and these scarcely admit of doubt as given in Mr. Leigh's reports), there can hardly be a question. It is the view of a statesman grafted on that of a public health reformer. But, meanwhile, what remains of the old cottage dwellings of Manchester shocks every sense of residents there who take an active interest in the sanitary reform of the city, and who are not prepared to relegate attempts at amendment to an indefinite future. They regard with irritation the refusal of the Corporation—unlike other great towns, Birmingham for example—to take advantage of general or special Acts of Parliament for clearing areas covered by unhealthy houses, and erecting thereon, or permitting others to erect, model dwellings for the labouring classes. They would anticipate the natural progress of the changes on which the Corporation depends. They have a righteous impatience of delay which begets every sympathy in view of the evils which they would eradicate; and, incited by

Dr. Arthur Ransome and others, they have taken the inhabitants generally into consultation with them, and after a fashion declared war against the Corporation notions. The form which this movement has assumed gives little hope that it is sympathised with to any large extent in Manchester, or that it will lead to any marked result in accelerating changes which both the Corporation and the citizens must desire to see completed. It has resulted in a proposition to form a limited liability company for providing improved dwellings for the labouring classes, with a capital of £20,000 in 4000 shares of £5 each. This is modestly spoken of as looking "at least like a step to business." But in view of the magnitude of the task to be undertaken and of the wealth of Manchester, does not this seem rather like another version of the "mountain in labour"? At least it would indicate that the time for inaugurating this movement has been very badly chosen. In discussing the question of art and public park accommodation in Manchester, *The Times'* correspondent writes of the Corporation as being hampered as to means. We know how difficult it has been found by the managers of the Royal Infirmary to get together from the inhabitants a sum barely sufficient to effect absolutely necessary alterations in the institution presumed to be the most cherished in the city. On all sides we hear of a ridiculous inconsistency between the reputed wealth of Manchester and its incapability or unwillingness, in consequence of recent and continuing bad times, to contribute to charitable and philanthropic objects within its own boundaries. We prefer to assume that the petty result of the labourers' improved dwellings movement is another indication of the "hard times" in the district than the result of indifference to the question sought to be solved. That the movement is inadequate to a solution of this question should be obvious, but that it might aid in ameliorating some of the most painful aspects of it, and helping importantly to the final result sought, does not admit of doubt.

Correspondence.

"Audi alteram partem."

THE IMMEDIATE TREATMENT OF STRICTURE OF THE URETHRA.

To the Editor of THE LANCET.

SIR,—As it has been suggested to me that some misconception might arise respecting the two deaths mentioned in my letter of last week, I take the earliest opportunity of stating that I only referred to those mentioned by Mr. Wood. There was another death in King's College Hospital in which a false passage was found extending through the neck of the bladder, but this was published years since; and the two deaths that occurred in the Westminster Hospital, also years ago, both resulted from kidney disease.

I have been fortunate enough not to have had a fatal case in private.

Very faithfully yours,

Savile-row, Sept. 20th, 1880.

BARNARD HOLT.

To the Editor of THE LANCET.

SIR,—I am glad to see that Mr. Barnard Holt has defended his method of treatment of stricture from the aspersions unfairly cast upon it. Having witnessed the great success of Mr. Holt's method whilst his colleague at the Westminster Hospital, I have continued to adopt the proceeding in suitable cases ever since, and I am well satisfied with it. Mr. Holt does not profess that his operation will "cure" what is acknowledged on all hands to be practically an incurable disorder; but I believe with him that a "split" stricture contracts less rapidly than one dilated or divided, and that when it has been allowed to contract it can be readily restored to full size. Since it is allowed that in cases of old-standing stricture, with disorganised kidneys, the mere passing of a catheter may kill by inducing suppression of urine, it is not surprising that death may occasionally follow the use of Holt's dilator under similar circumstances, as occurred to a private patient of my own two years back.

Again, if the dilator unfortunately enters a false passage, which is then split up, a consequent death cannot be fairly attributed to the method, though it may be to the operation.

I have before me the very carefully compiled printed annual Surgical Reports of University College Hospital for the last nine years, in each of which a special table of cases of stricture is given. I have collated these carefully, excluding only cases of extravasation of urine (admitted as such), and cases in which no treatment was adopted, with the following results:—

Treated by dilatation	157 cases with 13 deaths.
" internal urethrotomy 130	" 7 "
" external urethrotomy 18	" 4 "
" Holt's method . . . 32	" 4 "
" other dilators . . . 8	" 2 "

Total cases 345 " 30 "

It should be mentioned that the cases of internal urethrotomy include a large number of cases of simple "meatotomy," and also operations by various methods. I believe I may claim nearly all the "Holt's," and certainly the four deaths, two of which were due to false passage, and two to pyæmia. It should also be understood that Mr. Erichsen and Sir H. Thompson gave up all charge of patients early in 1875.

Your obedient servant,

CHRISTOPHER HEATH.

Cavendish-square, Sept. 20th, 1880.

To the Editor of THE LANCET.

SIR,—Being the surgeon who first introduced to the notice of the profession in this city Mr. Holt's plan of treating stricture, perhaps you will kindly permit me to say a few words on the subject, and to place on record in your pages the result of my experience of a number of cases, now to be counted, not by units but by hundreds. During all the years I have treated stricture on the immediate plan I have never had one fatal case, nor have I ever witnessed any more untoward consequence of the operation than, in some very exceptional cases, rigors. Every surgeon of experience has met with individuals who could not tolerate the attempt to introduce an ordinary instrument without, as the result, the supervention of rigors. Cases of this kind have come under my care, yet in many of these have I used Mr. Holt's plan without rigors ensuing. This I account for by my having used proper precautions and treatment. Early in this year a gentleman, a victim to stricture, consulted me. That his case was one of no ordinary difficulty can be certified by a gentleman who deprecates in no measured language Mr. Holt's plan of treatment, under whose care the patient was for some weeks in London. Every attempt to introduce an instrument was followed by such spasm as for hours to render him unable to void one drop of urine. I placed him under the influence of methylene, introduced the dilator, and forcibly dilated his stricture to such an extent as to allow of the passage of a No. 10 catheter (Weiss's gauge), a sized instrument which he is now able to pass for himself; yet he did not experience the slightest subsequent trouble. This gentleman called on me within the past week, and told me that, though a perfect stranger to Mr. Holt, he had twice called at his house, but was not fortunate enough to see him; the object of his visit being to express his gratitude to Mr. Holt for having introduced a plan of treatment whereby a life of misery had been converted into one of thorough enjoyment.

That fatal results may be ascribed, but erroneously so, to Mr. Holt's treatment, will be illustrated by what I am now about to state. Last month I had arranged to operate on two cases of stricture on the same morning in the Meath Hospital. On arrival I found one of the patients "seedy," and accordingly put him back, but operated on the other, who left the hospital a few days afterwards master of a No. 10 gum-elastic catheter, which, before my class, he himself introduced into his bladder. But what became of the other patient? The same day he was carried out of the hospital dead. Double pneumonia—rapid effusion; and in spite of the most energetic treatment the poor fellow succumbed. Had I been imprudent enough to operate that morning on that man, doubtless Mr. Holt's operation would have been credited with (or rather discredited by) another fatal result.

In conclusion, I may be allowed to add that my operations

have been conducted in the presence of large classes of students in the Meath Hospital, as well as in private. Were my results less favourable than I have here recorded, there would be plenty of witnesses to bear evidence against the accuracy of my statements.

Your obedient servant,

RAWDON MACNAMARA, F.R.C.S.I., &c.,

Surgeon to the Meath Hospital and to the Westmoreland

Dublin, Sept. 18th, 1880. Lock Hospital.

To the Editor of THE LANCET.

SIR,—Having had some considerable experience in the treatment of stricture by sudden and forcible dilatation, I am anxious to corroborate the testimony of Mr. Barnard Holt, in your last impression, as to the safety and efficiency of that proceeding.

I wish to do so because in comparing it with internal urethrotomy it has, in my judgment, been rather unfairly treated by some of the advocates of the latter method.

The disparaging remarks to which I allude consist not so much in argument as in vague condemnation on account of its supposed dangers, and unsupported insinuations of bad faith on the part of those who practise it in concealing unfavourable results. Thus in the late discussion at Cambridge one speaker is reported to have said: "He entirely agreed with the remarks that rupture was a dangerous proceeding. He never did it himself, but he had seen a good number of cases that went to the bad from it, and believed that such a rupture must lead to a traumatic stricture of the worst kind." What these vague statements amount to is shown by Mr. Holt in his letter of last week.

Another speaker on the same occasion said: "There were surgeons who still practised immediate dilatation, and that they did so showed that they were but imperfectly acquainted with the rationale of the operation, and were not aware of the great mortality attached to it." This is certainly true as regards myself. I know little and care less about its rationale, but am content to judge it by its results; while as to the great mortality alleged, I shall disbelieve it until I see some evidence in its support.

The same gentleman further says that, "had the deaths which have occurred after forcible dilatation been published, the operation would long ago have received its *congé*; and he thought the advocates of that method had not acted straightforwardly in omitting to publish them." This is an imputation of bad faith which, entirely unsupported as it is, ought to be discountenanced as altogether out of place in a scientific discussion. I should like to know why this propensity to the *suppressio veri*, if it has any existence, should be supposed to appertain to those who use the dilator rather than to the urethrotomists.

My own experience of the treatment by forcible dilatation may be briefly expressed. I have practised it in all suitable cases of obstinate stricture, both in hospital and private patients for the last fifteen to twenty years, and though I have kept no numerical account, I can safely say that they amount by this time to many scores. In no single instance have I met with a fatal result, or with any subsequent symptoms which gave me cause for serious uneasiness. My experience, in fact, coincides exactly with that of Professor Macleod of Glasgow, who said at the late meeting at Cambridge, "that he had never seen any complication, and no possible danger, follow the use of Holt's dilator when used in cases fitted for it."

I constantly see my colleagues at St. Mary's Hospital using the dilator, but very rarely the urethrotome, and though I, of course, only speak for myself, I assume that they would not continue to use it if they found their cases dying or "going to the bad" in the manner that has been alleged.

I have no wish to decry internal urethrotomy. I have never practised it, and therefore cannot speak from personal experience, but I accept, without reserve, the statements of such authorities as Sir Henry Thompson and Mr. Berkeley Hill as to its satisfactory results and its freedom from danger. I adhere to immediate dilatation because I believe it to be a less formidable proceeding, and because if urethrotomy would do all its advocates claim for it, I do not see that I should get better results than I have been accustomed to obtain from dilatation.

Deaths may now and then occur, and serious consequences may follow, after either operation (as they may happen after

any surgical proceeding, however slight), but there is no evidence, that I know of, to show that dilatation is more liable to them than urethrotomy. Bad results will be exceedingly rare in both if cases unsuited to any operation at all are carefully excluded.

No treatment of stricture yet known, whether by gradual or forcible dilatation, by internal or by external urethrotomy, will prevent a recurrence of the complaint, unless the patient will persevere in the use of instruments for a lengthened period. But I have not myself found these relapses more early or more severe in the intractable cases demanding the immediate treatment, than in the milder ones which are amenable to gradual dilatation, or than the more severe ones which are subjected to external urethrotomy, as advocated by Syme, in which latter, as Sir H. Thompson observes, "the diseased structures constituting stricture have been entirely divided, and in a way more certainly complete than any internal urethrotomy can offer."

Very faithfully yours,

Norfolk-square, Sept. 20th, 1880.

JAMES R. LANE.

"SIR T. D. ACLAND ON HOSPITAL NURSING."

To the Editor of THE LANCET.

SIR,—I am obliged by your kind notice of my few words at Exeter on Hospital Nursing. I need some excuse for intruding on professional ground. I inherit from boyhood a deep respect for the profession. In and out of Parliament I have watched its welfare, or rather that of the nation, for forty years and more.

I ask your leave to explain that I did not mean to deny that there is a desire to introduce sisterhoods in hospitals. Of course I know what is in action at King's College and University Hospitals and elsewhere. My object was to take the first opportunity I could find, as a responsible man in a public position, to stem the torrent of misunderstanding about Guy's, which was current in my own neighbourhood and reacting on our excellent local hospital.

The circulation in *The Times* of a sneer about dress and prayers was accepted by a too credulous public as evidence of ritualistic aims and centralisation which have no place at Guy's. Religious cries are too often simply weapons of warfare in secular battles. The English laity generally find out the truth in time.

What is now needed is that the earnest endeavours of active governors to deliberate freely with able men should not be hampered by the dictation of private meetings pledging a collective body, or by public attacks on women and men who are not at liberty to defend themselves by controversy about their responsible duties in the journals. I had hoped some such result might have been reached before the critical 1st of October. I have worked hard to help it forward. I can only now ask you to allow me, as an individual governor, to appeal to the great body of Guy's men not to be led off on a false scent, to rally round their old school at the opening of this session, and to judge for themselves whether there is any hindrance in respect of medical science, or observation or practice in the way of the students or their teachers.

Your obedient servant,

THOMAS DYKE ACLAND.

Holnicote, Taunton, Sept. 18th, 1880.

"HOSPITAL ETIQUETTE."

To the Editor of THE LANCET.

SIR,—I think any unprejudiced person reading Mr. Ewart's letter on "Hospital Etiquette" must come to the conclusion that there must be a misunderstanding somewhere. Allow me a few lines in explanation of the matter.

The medical officer at our dispensary reported to my colleagues and myself that a case of scarlet fever, with stone in the bladder, was coming to us from St. Mary's Hospital, with the request that the patient might be returned to them for operation. An opinion was expressed that we ought not to accept the case under any restrictions; but no decision was come to, and the matter dropped. The next day the boy was admitted into hospital under my care, and was shortly followed by a hip case, with scarlet fever, from the same quarter. A few days afterwards, Dr. Lloyd Roberts and Dr. Walter called on me on the subject. The former said the stone case had been admitted under his

care, but he had made it over to his colleague, and asked me to send it back to St. Mary's when well of the fever, as Mr. Ewart was anxious to perform lithotomy. I replied "that personally I did not care who had the stone, but I would speak to my colleague, Mr. T. Jones, and I had no doubt if I did so he would waive any claim he might have." On another occasion, when Dr. Lloyd Roberts was in my house about another matter, I suddenly remembered the case, and said, "Oh, that stone case is doing well; I must remember to see about him for you." I also told the boy (aged ten) that he might tell his mother that when he was no longer infectious she might take him back to St. Mary's. Now, about this time it happened that Mr. Jones, in consequence of the illness of a relation, was a good deal from home, and was much taken up by other pressing engagements; I seldom saw him, and, most unfortunately, it entirely slipped my memory to set matters straight about the stone. A few weeks afterwards I left home at a short notice, and unluckily the operation was performed by my colleague in complete ignorance of my interview with Dr. Lloyd Roberts. On my return I was exceedingly annoyed with myself for not having left special directions concerning the case. I took an early opportunity of explaining to Dr. Lloyd Roberts what had happened, and expressed my great regret that I should have been so forgetful in the matter, and how I would willingly take upon myself the blame of what had occurred. I must say, Sir, that after thus expressing my regret I never for a moment expected to hear any more of the matter. I was surprised to hear that it had become a burning question of "hospital etiquette;" and still more astonished was I to read that Mr. Ewart had "learnt that from the first the Pendlebury staff never meant the boy to return to St. Mary's." Let me say at once this is untrue. The case was admitted under my care, and except on the occasion just referred to I never spoke to my colleagues on the subject. I am unaware of any decision affecting its destiny, and had I not forgotten to speak to my colleague I do not doubt it would have returned to St. Mary's.

Having thus apologised to Dr. Lloyd Roberts, to whom the case belonged, and who had specially called on me on the subject, what more, Sir, could I do? I am sorry Mr. Ewart was disappointed and annoyed, but if he is still angry I cannot help it; and if he still impute bad faith to me, I have no more apologies to make, and will willingly leave it to the "sentiments of the profession" to decide, to whom the "discourteous" and "ungenerous" apply.

I remain, Sir, yours, &c.,

Manchester, Sept. 21st, 1880.

HENRY ASHBY.

** We are glad to receive this explanation, which will, of course, close the matter.—ED. L.

"NEW INSTRUMENT FOR CLEFT PALATE,"

To the Editor of THE LANCET.

SIR,—Having read Mr. Furlong's description of his needle on the shuttle principle in THE LANCET of September 18th, I hasten to concede to him whatever credit may be due for priority of invention over the instrument on the same principle devised by me, a description of which appeared in THE LANCET of July 24th. I would also express my appreciation of the additional miniature blade for isolating the tissues during perforation, which is part of his instrument, and is a deficiency in my own which I was even now attempting to supply.

At the same time it is due to myself to state that, previously to forwarding my communication, I had taken every pains to ascertain whether the idea as it occurred to me had been already carried out. It was only after failing to discover any knowledge of such an instrument either on the part of those surgeons to whom I showed mine, or of the instrument makers, and after a vain search through every accessible record of surgical appliances, that I forwarded it for publication. This general ignorance respecting the existence of Mr. Furlong's invention cannot be wondered at, as he states "there is no published account" of it. I think, therefore, Mr. Furlong will have no cause to regret the step I took in calling attention to a needle on the shuttle principle, I being absolutely ignorant of his invention—inasmuch as my so doing has served to rescue him from the undeserved oblivion into which he had suffered it to lapse.

Respecting the points of divergence between the two in-

struments, whether the blades should be scissors or forceps, the method of fixing the needle on the one blade and of clamping it in the other, these are matters of detail concerning the respective advantages of which experience alone will enable a correct estimate to be formed. What is of more importance to know, and which Mr. Furlong's experience goes to prove, is that the irksomeness of cleft palate operations can be lessened by the use of an instrument which his ingenuity had already devised when I was labouring to attain it. Had it not been for Mr. Furlong's reservation of his skill I should have been spared this labour, and your columns the tedium of a personal explanation.

I remain, Sir, yours, &c.,

London, Sept. 20th.

ED. WOAKES, M.D.

A TONGUE-DEPRESSOR.

To the Editor of THE LANCET.

SIR,—In bringing forward the accompanying pattern of a tongue-depressor, I do not claim for it any undue amount of importance; but as it is a little instrument in frequent requisition, I have devised the present form, and, finding it so convenient after twelve months' use, send you a pattern for publication.

The advantages it possesses over the ordinary clumsy instrument are, that the tendency to retching is lessened by the smaller surface of metal inserted into the mouth. The tongue is not concealed by it; and with patients who have the knack of "hawing up" the tongue, the sides of the instrument, which press into its substance, admit of a view of the fauces, which would be impossible with the old instrument.

I have found it useful in the examination of the irritable throat of phthisis, where the ordinary mass of metal introduced into the mouth renders a view impossible by reason of the discomfort and irritation produced. It is light and portable, of much less cost than the ordinary form, and easily cleaned.

The woodcut represents one pattern with a handle for hospital use, and the other jointed for the pocket. These have been made for me by Mr. Goode, of Praed-street.

I am, Sir, your obedient servant,

ALFRED WISE, M.D.,

Sutherland-gardens, W.,
September, 1880.

Visiting Physician to the Infirmary for
Consumption, Margaret-street.

DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—In the spring of last year (1879) I attended during an outbreak of diphtheria a family consisting of five persons—viz., father, mother, two little children, and a young servant girl.

The servant showed symptoms of the disease on March 22nd; it ran a favourable course, and she was convalescent on the 29th.

The youngest child, aged two years and three months, was seized on April 13th, and died on April 20th.

The other child, aged five years, was taken ill on April the 18th; she recovered to some extent, but after lingering till May 31st she died from blood-poisoning and paralysis.

The mother also became ill on April 18th, but recovered; and the father escaped with the exception of slight sore-throat.

I myself contracted the disease whilst attending them, but had little more than the local symptoms, and was well in a few days. The drains were said to have been recently examined.

Owing to a leakage of sewage into the basement, it has just been discovered that the drains of this house and those of the next have one common exit into the sewer. The people next door, having had their water cut off more than three years ago, have since been using only what they could beg from neighbours, the natural result being the blocking up of the common drain-pipe, and probably causing the outbreak related above.

As under the present system of drainage this is a danger that may attack any of us, it does not seem to me unreasonable to ask whether the water companies, possessing as they do the monopoly of supplying us with what is a necessary of life, should be permitted to enforce payment of their rates by cutting off that supply, thus seriously endangering the lives of a whole neighbourhood, and, as in the present case, punishing not so much the defaulter as a man who owed them nothing, but who is, nevertheless, in all probability doomed to end his days childless.

I remain, Sir, yours truly,

Brixton-road, August 18th, 1880.

H. J. F. GROVES.

THE SERVICES.

MEDICAL OFFICERS FOR AFGHANISTAN.

The following medical officers of the Madras Army have been ordered to proceed on service to Afghanistan:—Surgeon-Majors A. C. Gaye, J. M. Cogan, E. A. Roche; Surgeons J. Mulrenan and A. Kirwan; also Surgeon-Majors F. C. Reeves, H. Jagoe, R. M. Bradford, John North, and J. Elcum, of the Indian Medical Service.

Surgeon-Major H. L. Bruce, Indian Medical Service, has been appointed Principal Medical Officer of the Reserve Division, Southern Afghanistan Force, with the temporary rank of Deputy Surgeon-General.

Deputy Surgeon-General Thomas Wm. Fox, M.B., has been appointed on promotion Principal Medical Officer of the North British District, Edinburgh, vice Deputy Surgeon-General J. S. Furlong, transferred to Nova Scotia.

The *Gazette of India* of the 14th August announces that the Viceroy has appointed Surgeon-Major J. M. Cunningham, M.D., Sanitary Commissioner with the Government of India, to be Surgeon-General Indian Medical Service, with permanent rank from the 29th March, 1880, in succession to Surgeon-General J. F. Beatson, M.D., retired.

ADMIRALTY.—Surgeon W. J. Lightfoot has been appointed to the *Serapis*.

INDIA.

(From an occasional Correspondent.)

DURING the early part of the hot weather an epidemic of diarrhoea, remarkable for the impartiality of its attacks, prevailed at Simla. As the disease did not, fortunately, prove fatal, people could afford to make light of the matter, and the "prevailing ep.," as the epidemic was familiarly called, became a standing joke, as "five o'clock beef-tea" at the club became a standing institution. So general was the epidemic, that it is stated more than 300 prescriptions for the complaint were dispensed by one druggist's establishment in one afternoon. Guests had to quit the dinner-table in a hurried and undignified manner, and at one large official dinner more than half the invited guests sent excuses at the last moment. A curious point about the epidemic was that

scarcely any children, and but comparatively few ladies, suffered. The new Simla water-supply was in some quarters accused of causing the outbreak, but the partiality shown by the disease would indicate some other cause. The Army Sanitary Commission, which appears to be little else than the Sanitary Commissioner with the Government of India "writ large," has given publicity to some astonishing statements which (I am glad to see) have been challenged by a writer in the *Pioneer*, August 7th. The Sanitary Commissioner states: "It is no part of our duty to enter on etiological controversies, but when facts of this kind present themselves it becomes our duty to call the attention of the authorities in India to them, and to point out that the occurrence of cases of cholera among the population using Vehar water and the high death-rate among them are in direct contradiction to the water theory. This fact has been already recognised by the Calcutta authorities, and, fortunately for the advance of public health improvements, the Indian authorities are too acute to be led astray by European disease theories, and they know how to deal with theorists. Calcutta and Bombay have both better water supplies than London, and both suffer from cholera." This writer remarks:—"The commission do not seem to be aware that large tracts of Calcutta lie outside the field of the new water supply, and that most of the cholera deaths that now occur take place among the poor and dense populations who reside on these tracts. But even within the field of supply the difficulties under which the poorer classes lie in getting the filtered water are so great that a large quantity of very foul water is in daily use among them. Referring to an outbreak of cholera in Hastings-street, Calcutta, the health officer, in a recent report, thus writes: 'A police guard was stationed on the bank (of Tolly's nullah), not to prevent bathing, for this was out of the question, but to caution the people against the further use of the water. The engineer was ordered to prepare estimates for doubling the number of hydrants.' This nullah, in which tens of thousands of people bathe, from having no better water convenient for the purpose, is little better than a foul sewer. Its water is defiled by the drainage of many public and innumerable private latrines, and by the discharge of many sewers which do not communicate with the new main sewer. Another defect in the new water supply arrangements is that the supply is turned off at night, and the consequence of this is that careless, improvident people, who have no storage arrangements, have to resort for water after sunset to the innumerable foul tanks on which Dr. Payne has been waging a noble war of extermination for some years. Such is the water-supply which the Army Sanitary Commission—in its eagerness to discredit 'European disease theories,' propagated and popularised by men like Parkes and Simon—say is better than the water-supply of London! I lately heard of a remarkable testimony to the value of the new Calcutta water-supply in preventing cholera. It was that of the chaplain whose duty it was to minister at the burial of Europeans. This gentleman noticed that with the introduction of the new water his work suddenly became much less, owing to the almost entire cessation of cholera among European residents, as the disease was now nearly confined to the sailors living on the river, who continued to use the Hooghly water as before."

What the condition of the Bombay water-supply was during the hot weather of the present year is best seen from the following extract from the *Times of India* (*Pioneer*, July 22nd, 1880): "The almost complete failure of the Tulsī water system during the past hot season, and the narrow escape which the city had from the evils and inconveniences of a water famine, have naturally excited much attention. Even in the early part of May the enormous quantity of water which had been drawn off from the Tulsī lake had reduced the water to an alarmingly low level; and as the month wore on it became more and more apparent that, unless the strictest care was exercised in the distribution of the water in hand, a total stoppage of the supply was imminent. Consequently the water was only admitted into the city at certain short intervals, and then in comparatively small quantities. As day succeeded day, and as the level in the lake got to be lower and lower, it became more manifest that unless the rains arrived at an early date the city would be subjected to a dearth of water

¹ A watercourse.

during a period when pure and wholesome water was most essential to the well-being of the people. As the end of the hot season approached, the quality of the fluid sent through the mains into the city was very bad, and the bath tubs of households were charged with a quantity of solid matter which could not be separated from the water by any amount of filtration. The Vehar supply was called in to supplement Tulsī, and in this manner the supply was kept up until the 5th of June, when the monsoon burst, and a heavy fall of some five inches of rain in two days relieved the anxiety of the municipal officers. Of course, such a glaring failure of the water-supply was not to be allowed to pass without comment: Dr. Weir, the Acting Municipal Commissioner, has succeeded in proving that up to the present there was no ground for saying that there had been any miscalculation as to the nature of the Tulsī supply. It has been urged, and with great show of reason, that until the Malabar Hill Reservoir, which is an important part of the Tulsī scheme, has been completed, it is impossible to judge as to the capabilities of the project for supplying the city with water, and that, until the system is carried out in its entirety, any condemnation of the work would be unfair."

Cholera has been prevalent in the Lucknow and Allahabad Districts. The 2-22nd Regiment, stationed at Allahabad, has lost thirty-five men in all. On the 31st of July the epidemic threatened to assume serious proportions, no less than sixteen men and one officer—a young A. M. D. surgeon, Dr. Noad—having been buried on that day. Dr. Noad's case was a sad one. He was a Charing-cross man, who had only arrived in India in March; he was in delicate health, and under the heavy work he succumbed. He was attacked at 2 A.M., and died at eight o'clock next morning, much regretted by all who knew him. He fell at his post.

The outbreak in the 22nd presented some interesting etiological features; but at such times as the onset of an epidemic medical officers have no leisure to institute inquiries into the circumstances connected with the outbreak. The disease was for some days confined to the European infantry, although between it and the native city, where cholera prevailed largely, lay a battery of artillery, which only had one case, and that some ten days after the outbreak in the infantry barracks. Immediately to the north-east of the infantry were the Native infantry lines, where no case of cholera appeared until after the solitary one in the artillery. Every barrack of the 22nd, excepting the hospital, seems to have furnished cases indiscriminately, excepting the two hospital barracks. The women and children also were quite free from cholera. These conditions would, therefore, appear to be strongly opposed to any epidemic wave hypothesis, and they tend to indicate to me food or water contamination as the cause, to which the men of the regiment only, with the important exception of the hospital patients, were exposed. Such a cause might exist in connexion with the canteen, to which all the men, excepting the hospital patients, had access. No officer, excepting Dr. Noad, was attacked. It is stated that at the time of the outbreak there was plenty of money among the men, owing to many of them having re-engaged, and having received the usual bounty.

A TABULAR VIEW OF THE DAYS AND HOURS OF THE INTRODUCTORY LECTURES

To be delivered at the different Medical Schools.

	Lecturers.	Days and Hours.
St. Bartholomew's Hospital	(No Lecture)	Oct. 1st
Charing-cross Hospital	(No Lecture)	" 1st
St. George's Hospital	Dr. Cavafy	" 1st, 4
Guy's Hospital	(No Lecture)	" 1st
King's College	Prof. George Johnson	" 1st, 4

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Sept. 16th:—

Dacachauji, Edalji Rustauji, Bombay.
Kinneir, Francis William Edward, Doughty-street.
Lane, Alexander, Bishop's Castle, Salop.
Wasse, Gervas Miles, Newton, Devon.

The following gentleman also on the same day passed his Primary Professional Examination:—
Harris, John Harry, Guy's Hospital.

At the Preliminary Examination in Arts held at the Hall on Sept. 17th and 18th, 145 candidates presented themselves, of whom 47 passed and received certificates of proficiency in General Education—viz.:

FIRST CLASS.
Florence Nightingale Toms.

SECOND CLASS (in alphabetical order).

C. A. Adams.	R. B. Leggatt.
R. H. Barrett.	C. E. Liesching.
E. D. Bell.	Emma M. D. Miller.
F. Brightman.	Paul von Nordeck.
E. H. Brock.	G. C. H. Norman.
G. T. Cattell.	A. C. A. Packman.
Kate Crooke.	Jiteudja N. Pálit.
H. W. Denton-Cardew.	T. J. Palmer.
R. Dobson.	E. W. Paul.
T. U. Duer.	W. J. Procter.
W. B. Felton.	Edmund Raghib.
G. W. H. French.	H. V. Rake.

W. M. Joyce.	S. Wachter.
H. H. Kent.	J. J. Wheeler.
H. B. Lavies.	F. A. Yonge.

MR. PARETTE, surgeon, of Beaufort, Breconshire, was, on the 14th instant, presented with an illuminated address and a massive gold Albert by the workmen and inhabitants of Sirhowy and district, in recognition of long and valuable services.

THE annual dinner of the East-end Tradesmen's Association in aid of the London Hospital was held on the 16th inst. The chairman, Mr. Dix, stated that the members of the society now numbered 311, and that its efforts had resulted in the addition of something like £1500 to the funds of the hospital.

ANOTHER death from shock, apparently resulting from wasp-stings, is reported. A woman, aged sixty-one, residing at Langham, near Colchester, in picking grass from the roadside disturbed a nest of wasps, and was stung on the forehead. On her return home her head became much swollen; she fell into unconsciousness, and shortly afterwards expired.

THE ISLINGTON WORKHOUSE.—The excellent and courteous medical officer of the Islington Workhouse, Mr. Philip Cowen, has lately resigned his post, to the great regret of the inmates of the workhouse, who had in him a careful and wise adviser, and of all medical men whose duties brought them into occasional contact with Mr. Cowen. Mr. Cowen had also the pleasure to receive a substantial proof of esteem from his fellow officials in the institution. He leaves the workhouse to commence private practice. The guardians have shown their respect for him in giving him the charge of an outside district.

BEQUESTS ETC. TO MEDICAL CHARITIES.—Mr. Peregrine H. Purvis, late of Winchmore-hill, bequeathed £100 each to the Royal Free Hospital, the Metropolitan Free Hospital, the British Home for Incurables, the Earlswood Asylum, the City of London Hospital for Diseases of the Chest, and the Deaconesses' Institution and Training Hospital, Tottenham. By the will of Mr. John Rahles, late of Camden-road, the German Hospital, Dalston, becomes entitled to £200. The managers of the Metropolitan Convalescent Institution have received from an anonymous donor the sum of £6500, on condition that they at once establish a seaside convalescent home. Miss Fanny Brookman, of Sandford, Winscombe, bequeathed £500 to the Weston-super-Mare Hospital, and £1000 to the West of England Sanatorium.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

- ADRIEN, E. N., L.K.Q.C.P.I., has been appointed Medical Officer to the Balbriggan District of the Balrothery Union, vice McEvoy, resigned.
- BUCKENHAM, J., L.R.C.P.Ed., M.R.C.S.E., has been appointed Public Vaccinator for the Borough of Cambridge, vice Knowles, deceased.
- DALE, B. H., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer to the Arncliffe District of the Settle Union.
- ENGLAND, W., M.D., F.R.C.S.E., has been appointed Medical Officer to the First District of the New Winchester Union.
- HAMMOND, G., L.D.S.R.C.S.E., has been appointed Dental Surgeon to the Western General Dispensary, Marylebone-road.
- HARRISON, H. F. E., L.R.C.P.L., M.R.C.S.E., has been appointed Public Vaccinator for No. 2 District of the Fulham Union.
- KNOWLES, E., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the First District of the Cambridge Union, vice Dr. Knowles, deceased.
- MAGNER, E., M.D., M.Ch., L.M.K.Q.C.P.I., has been appointed House-Surgeon to the Cork Workhouse, vice Riordan, resigned.
- PENTLAND, A., M.B., L.R.C.S.I., has been appointed Medical Officer to the Ryan Dispensary District of the Mohill Union, vice Creery, resigned.
- POLAND, J., L.R.C.P.L., has been appointed Registrar to the North-East Hospital for Children.
- PORRITT, N., M.R.C.S.E., has been appointed House-Surgeon to the Huddersfield Infirmary, vice Evans, resigned.
- ROWNTREE, W. G., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Barnsbury District of the Islington Union, vice Hurston, resigned.
- SOUTHEY, A. J., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Slough Urban Sanitary District for three years. £25 per annum.
- STEELE, R., L.R.C.P.Ed., M.R.C.S.E., has been appointed House-Surgeon to the North-East Hospital for Children.
- STEVENSON, T., M.D., F.R.C.P.L., has been appointed Public Analyst for the Borough of Godalming for one year.
- WALSH, P. C., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Frenchpark Dispensary District of the Castlereagh Union, vice Gillespie, resigned.

Births, Marriages, and Deaths.

BIRTHS.

- BUCHANAN.—On the 16th inst., at Paddock House, Chatham, the wife of Walter Buchanan, M.R.C.S.E. &c. (prematurely), of a daughter.
- ELLIOTT.—On the 14th inst., at Mansfield, Notts, the wife of Thomas Elliott, M.D., of a son.
- GRIMBLY.—On the 9th inst., at Newton Abbot, South Devon, the wife of Richard Henry Grimbly, M.R.C.S.E., of a daughter.
- GUNNING.—On the 13th inst., at Silverdale, Staffordshire, the wife of John Edmund Gunning, M.R.C.S.E., of a son.
- MOORE.—On the 13th inst., at Roker-terrace, Sunderland, the wife of Dr. George Moore, Fleet Surgeon, Royal Navy, of a daughter.
- PARAMORE.—On the 13th inst., at Hunter-street, Brunswick-square, the wife of Richard Paramore, M.R.C.S.E., of a daughter.

MARRIAGES.

- COLBOURNE—KRABBÉ.—On the 7th ult., at St. John's Church, Buenos Ayres, Louis Colbourne, M.D., to Nora, third daughter of the late Charles Brehmer Krabbé, Esq.
- MACREADY—DAVIDSON.—On the 1st inst., at the Parish Church of St. Marylebone, Jonathan F. C. H. Macready, Esq., F.R.C.S.E., of Harley-street, to Fanny Sarah, youngest daughter of the late James Davidson, Esq., of the Bengal Civil Service.
- PARISH—ANDERSON.—On the 9th inst., at Christ Church, Erith, Kent, Frank Parish, M.R.C.S.E. & L.R.C.P., of Worthing, Sussex, son of John Parish, Esq., of Erith, to Emma Frances, eldest daughter of William Anderson, Esq., C.E., of Erith.
- PHILLIPS—TOMS.—On the 4th inst., at St. Abbot's, Kensington, George Bagster Phillips, M.R.C.S.E., of Spital-square, Norton Folgate, to Lizzie Toms, of Dorset Villa, Campden-hill, youngest daughter of the late John Toms, of Chard, Somerset.
- RENNER—BERTLING.—On the 2nd inst., at Portsdown-road, Charles Renner, Esq., M.D., to Emma, eldest daughter of Robert Bertling, Esq., M.D.

DEATHS.

- BREEZE.—On the 5th inst., at his residence, Park Lodge, Finchley, Richard Goodwin Breeze, Esq., M.B., M.R.C.S.E., only surviving son of the late Rev. Richard Breeze, aged 46.
- DAVIES.—On the 5th inst., in London, John Davies, M.D., late Surgeon to the Ebbw Vale Iron Works, aged 60.
- IMRAY.—On the 22nd ult., at his residence, Saint Aroment, Dominica, West Indies, the Hon. John Imray, M.D., much loved and deeply regretted. Friends will please kindly accept of this intimation.
- REID.—On the 20th inst., at Moira House, Arnold, Notts, Alexander William Reid, M.A., M.B., C.M. Glasg., L.R.C.S.Ed., aged 31.
- STOKES.—On the 18th inst., at Clanciarde gardens, Bayswater, London, John Milbourne Stokes, M.D., of Milbourne, Hawke's Bay, New Zealand, aged 67. New Zealand papers, please copy.
- STOLTERFOTH.—On the 19th inst., at Queen's-park, Chester, Sigismund Stolterfoth, M.D., F.R.C.P., late of Dover, in his 85th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

OBLIQUE INCISIONS.

At a recent meeting of the Philadelphia Academy of Surgery, Dr. Packard called attention to the advantage of oblique cutaneous incisions, not only in avoiding scar, but in promoting immediate union. Though the method is no novelty, the hint may be useful to young surgeons elsewhere than in America.

J. G. S.—We believe our correspondent's qualifications would be admitted for the appointment; but it would be best to write to the Secretary of the Local Government Board (Ireland), Dublin, and ask for a copy of the Regulations concerning the appointment of Union medical officers.

D. M. R.—We know of no institution of the kind, except perhaps the Ladies' Charity School, 22, Queen-square, W.C.

EFFECTS OF AN EXCLUSIVE MEAT DIET.

To the Editor of THE LANCET.

SIR,—Can any reader of THE LANCET kindly supply me with information on an experiment tried at the Gobelins? The experiment was to feed criminals on exclusive meat diet. They died in a few days. Any information on the subject, or an account of this particular case, will oblige,
Yours truly,

Sept. 14th, 1880.

DIETETIC.

* * We are not acquainted with the particulars of the experiment alluded to by our correspondent. The exclusive use of a meat diet could hardly be fatal in a few days. The first serious result would be the development of scurvy, and it is hardly to be supposed that, after the serious symptoms which accompany the disease had manifested themselves, the experiment would have been pushed to a fatal conclusion. In an experiment, however, made on dogs, a diet consisting of purely proteid material, such as dried fibrin or coagulated albumen, proved speedily fatal, since these substances do not contain the fatty principles and extractives found in ordinary meat, and which thus render it a fairly representative food. Dogs fed exclusively on Liebig's extract were found to die sooner than dogs not fed at all. This has been accounted for as due to the deleterious influence of the potash salts of the extract; for, though these are indispensable to the economy, a large dose of them is injurious in the absence of the food whose metabolism it is their office to direct. For the latest particulars with regard to the physiological effect of meat diet, we would refer our correspondent to Professor Foster's "Text-book of Physiology," and to some observations made on this point by Dr. Ralfe, and published by him in our columns, 1877, in a contribution entitled "An Inquiry into the General Pathology of Scurvy."—ED. L.

A CHINESE OPINION OF WESTERN MEDICAL PRACTICE.

The *Foochow Herald* publishes the following translation of an article from a Mandarin organ. The portrait of the European practitioner of medicine is certainly not flattering:—

"The reason why foreigners adhere to their own system is because they are well aware that China and foreign lands are different, that the constitutions of the people and medicines and climates are like wise different, that the countries are thousands of miles apart, the languages and tastes are also dissimilar, and that under these circumstances the medical practice cannot be the same. Otherwise, with their intelligence, western nations would have had no difficulty in learning anatomy on Chinese principles, and would have adopted our ancient system. It is because they do not understand our principles that they retain their own medical science for their own use. But our people do not understand the foreigners' principles, and we do not want to borrow foreigners' science to cure us. In so doing we are stupid and mistaken, whether that science be good or bad. As people say, they are foolish doctors who cheat others. Because they know nothing of the pulse, they delight to copy foreigners who pay no attention to the pulse; because they know nothing of the nature of drugs, they delight in western science, which does not inquire into the nature of drugs. They (the foreigners) force upon their patients pills, powders, plasters, and potions, without knowing anything about them. They never adopt the plan of writing out descriptions of cases. In their surgical practice they cut, slice, chop, and hack in the cruellest manner. They perform the most horrible and disgusting of operations with the nonchalance of a juggler playing with his ivory balls, utterly regardless of their patient's life. The proverb that it is no good to cure a disease if you kill your patient applies to them thoroughly. These doctors are just like executioners, except that the latter kill by order those who ought to die. The former with a turn of the wrist calmly and coolly kill those who have done no wrong, but have merely asked to be cured of some disease. Neither heaven nor mankind can be insensible to this, which is insupportable, if there be anything that is insupportable. The desire of heaven and earth is to give life to men; the wish of princes and rulers is to preserve it. These people make a business of killing men, and do so under the pretence of saving their lives. They should be happy that they are able to remain upon the earth."

Vertebra.—By the reading of the Regulations, it would appear that both examinations must be passed. Application might be made to the Secretary.

Zymotic.—The paper will appear in an early number.

Mr. Buckland.—We do not prescribe.

THE CASE OF MR. O'BRIEN JONES.

To the Editor of THE LANCET.

SIR,—The case of Howell v. Jones and West must be fresh in the recollection of your readers, and I think only requires increased publicity in order to obtain for Mr. Jones such a response as will fully compensate him for the pecuniary loss he has sustained—viz., £500. The following sums have already been received:—

Special Donations.

The Rev. B. B. Bockett, Vicar of Epsom ..	£10	10	0
Mrs. Bockett	10	10	0
R. Brooks, Esq.	21	0	0
H. Brooks, Esq.	10	0	0
J. E. Erichsen, Esq.	10	10	0
Dr. Drage Hatfield	10	10	0
	72	10	0
Subscriptions to this date	187	15	6
	£260	5	6

I trust you will allow me by the insertion of this letter to invite further subscriptions, which will be duly acknowledged by,

Yours obediently,

ED. HART VINEN, M.D., Treasurer.

17, Chepstow-villas, Bayswater, Sept. 20th, 1880.

"EASY EXPULSION OF GALL-STONES."

To the Editor of THE LANCET.

SIR,—Dr. Roderick Kennedy's communication on this subject, which appears in to-day's LANCET, deserves some comment. Dr. Kennedy states that in every case in which gall-stones were proved or presumed to be the cause of periodic suffering, and in some instances in which there was merely obstruction to the proper flow of bile, the administration of large doses of olive oil was followed by prompt and painless expulsion of a surprising number of gall-stones. It is probable that Dr. Kennedy might have obtained equally surprising results if he had administered similar doses of oil to persons who had no liver symptoms whatever. Dr. Kennedy has offered no satisfactory proof that these bodies which were expelled in such a wholesale and painless manner were really gall-stones. A reference will be found in Flint's Practice of Medicine, fourth edition, page 460, to cases where enormous numbers of fatty concretions were passed after administration of large doses of olive oil given with a view to expel gall-stones. At all events a treatment followed by such tangible results must needs be very comforting to the patient's feelings.

Yours truly,

JAMES B. BALL.

Brixton, Sept. 18th, 1880.

GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.

We regret that, through an inadvertence, the above institution was omitted from the tabular list of Scotch Medical Schools in our Students' Number. Most of the information regarding the Glasgow School of Medicine was, however, comprised in a paragraph on page 446 of that number, to which we would refer our readers.

Dr. Alderson.—1. The age of the patient does not militate against his being the subject of typhoid fever, as this disease has been met with in subjects over forty years of age.—2. The toxic effects of quassia upon man and the higher animals was discussed by Pereira, and the history of the case recorded in the "Mirror" for August 14th leaves no room for doubt as to the symptoms exhibited being due to the drug.

Mr. W. W. Vinnedge.—Mr. Erichsen has written a work on the subject. *Zero* and *D. M. R.* have forgotten to enclose their cards.

"LEGALISED QUACKERY AND LOW CHARGES." A DEFENCE

To the Editor of THE LANCET.

SIR,—Much has been written and said against the self-supporting dispensaries and the doctors attached to them; but I think the arguments that have been brought forward against them have been very fairly refuted by those most interested. I should wish to try to make some defence to the hostile criticism that appeared in your journal a few weeks since. The self-supporting dispensary is now an established institution. The numbers that have sprung up in all parts of the metropolis, and the general success attached to their establishment, stamp the fact plainly that they were required to meet a want amongst the poorer classes. In few neighbourhoods where they have been established can it be shown that the general practitioner is injured or that any chemists' shops have been closed, and no better argument can be advanced as to their utility and benefit than this general success and non-injurious effect upon the general practitioner or the legitimate part of a chemist's business. The scathing pen that writes down the self-supporting dispensary doctor abuses a very useful member of society, and does not take into consideration "the times," and that these institutions and the men for them have sprung up to supply a great and general want—viz., good advice and medicine cheap, and without in one sense "charity." As well might the practitioner who has club and union practice be abused. I have been associated with large club and union practices as well as dispensary work, and my experience is that the dispensary doctor is equally able, if not much more so, to give time, attention, and good medicine to his patients as is the club and parish doctor to his; and although there is this difference, that clubs and union appointments are mostly held to work in with private practice, I doubt if the club and union patients get the better attendance or physic supplied to them for that reason, and I would wish to ask the club doctor if the average club, which includes women and children, pays him 1s. per visit and 6d. for each bottle of medicine supplied to the sick members? yet clubs are seldom refused by the general practitioners, even in good practice, and are not unfrequently canvassed for. Then as to the impossibility to supply good medicine (in fact all that is necessary) for 6d.: I maintain it can be done, as anyone will admit who has a knowledge of the working of dispensaries, whether self-supporting or supported by voluntary contributions. The drug bill for a dispensary paying £500 a year need not exceed £70 per annum. The dispensary doctor is better off than the average rural practitioner, whose work and expenses are frequently wholly out of proportion to his receipts.

The popularity of the "dispensary" in the profession is clearly proved by the eagerness with which they are purchased when offered for sale—purchased not only by men with inferior qualifications, but by those who have distinguished themselves at their hospitals at the different examining boards. They are used as stepping-stones to better things, and many a man, who will in time to come stand well in the profession and with the public, will have to thank the ready-money dispensary for helping him to bear the heat and burden of the day.

Lastly, the old-fashioned medical etiquette is a thing of the past. Many of our leading surgeons and physicians do not hesitate to usurp the duties of the general practitioner. They certainly do not set a good example to the struggling, striving mass of professional men at the bottom of the ladder. We must live, and in this crowded, competing world of ours it will not do to stand and starve because such-and-such a thing is not professional according to the lights above. Without doubt the dispensary is a necessary institution, and before the medical men attached to them are so ruthlessly condemned, it would be well to inquire into and see the work done; for, believe me, many there are of us who are honestly and earnestly working in our humble way, often without fee and without appreciation, always with the hope of alleviating the suffering and distress around us, and at the same time for the support of ourselves and family.

August 24th, 1880.

VULCANITE PLATES.

L.R.C.P. Ed.

DR. SEXTON, in a recent paper in the *American Journal of the Medical Sciences*, states it as his opinion that the wearing of vulcanite plates in the mouth is productive of conditions that frequently give rise to reflex aurial disease.

Mr. E. S. Scott.—Ellis among English authors; or Smith or Meigs and Pepper among American authors.

M. M. Heron.—We have no knowledge of the individual.

Dr. Percy Boulton.—Soon.

*Dr. G. W. Parker, (Madagascar).—*1. Reports on Disinfectants will be found in THE LANCET of July 26th and August 9th, 1873. Sulphurous acid, chloride of lime, carbolic acid, and chloride of zinc are amongst the best. — 2. We shall be glad to receive the paper referred to. — 3. The problem has not been solved so far as we are aware, and would form an important subject for observation and inquiry.

*Mr. Hope, (York, W. Australia).—*The papers have been received, and are marked for insertion.

*Candidate.—*See the Students' Number of THE LANCET, September 11th.

CHLORAL AND MORPHIA.

To the Editor of THE LANCET.

SIR,—In THE LANCET of March 6th of this year you were generous enough to publish a letter of mine upon "Serious Collapse from Chloral and Bromide of Potassium combined with Opium." The lamented death of Mr. Amphlett is another illustration of the fatal result of the ingestion of these drugs. The late Mr. Amphlett, whilst yet conscious, declared that he had not taken an overdose of any drug. His statement I feel sure is correct. It is the ordinary doses of the one following that of the other that produces so fatal a condition. One of the cases I alluded to in my letter of the 6th of March is somewhat similar to the late Mr. Amphlett's. The patient, a young man, had been delirious for some time. Chloral hydrate had been given without any beneficial effect. A second opinion was called in, and it was decided to give a subcutaneous injection of morphia of one-fourth or one-sixth of a grain. The patient soon became quiet, livid, and died in two hours. The doses were not above those usually given, yet death followed. The late Mr. Amphlett's almost last words were that he had not taken an excessive dose of medicine. The case given above will bear out the truth of his statement.

Yours obediently,

PETER W. DE LA MOTTE, M.R.C.S. Eng.

Staines, Middlesex, September, 1880.

*G. M.—*All advertisers are to be avoided as men outside the pale of professional intercourse.

"MEDICAL ETHICS AND PRACTICE IN NEW ZEALAND."

To the Editor of THE LANCET.

SIR,—Under the above heading in your issue of Sept. 4th is a letter signed "Doctor," dated New Zealand, Dec. 1879. As the New Zealand medical men can hardly be expected to take notice of a letter bearing an assumed name and giving no details, I think it only fair towards that body of men to ask you to insert this letter.

I was in Christchurch, New Zealand, in November and December, 1878, and had occasion to call in two medical men of that town in consultation over a patient with whom I was at the time travelling. Both of these gentlemen exhibited the most perfect acquaintance with the ethics and etiquette as usually followed by our leading London physicians and surgeons, and, in addition, went out of their way to be courteous to me as being a stranger, as well as being a professional brother. During my short stay in Canterbury colony I met several other medical men, and in all cases was very pleased to see the high standard of ethical bearing taken by our colonial confrères. I can assure you it would contrast very favourably with that commonly exhibited in this country. In Melbourne and Sydney I can also attest to the high position and delicate appreciation of points of ethics shown by the leading medical men. There are, of course, numerous quacks and bad cases of advertising; but the respectable people in the colonies never patronise such men, and know quite well the value of being treated by men who appreciate a good code of ethics.

Yours faithfully,

London, S.W., Sept. 18th, 1880. J. KINGSTON BARTON.

COATED PILLS.

To the Editor of THE LANCET.

SIR,—I should like to call the attention of your readers to a matter which has lately come very prominently under my notice. I refer to the use, among dispensing surgeons, of the coated pills as usually supplied by wholesale druggists. It has been my custom to have a certain number of pills of various formulæ made up and coated by my wholesale druggist. On several occasions these pills have hardly acted as one would have wished, and the other day the following occurred:—A patient consulted me, who appeared to be suffering from an attack of dyspepsia. I prescribed a tonic mixture to be taken three times a day, with one aperient pill (coated) with each dose of the mixture. In two days the aperient effect was nil. I repeated the mixture, substituting pil. cathart. fort. for the pil. aperiens. After having taken thirteen of these with no aperient effect, it occurred to the patient to divide two of the pills. This was followed by considerable disturbance of the bowels. The patient having told me of this, I made up two pills of the same nature, and these, too, were followed by markedly aperient effects. The question, therefore, naturally arises: Is it possible that coated pills in many cases are never dissolved at all? If this be so, surely it gives rise to a question of no little importance, taking into consideration the enormous number of coated pills that are used in the present day.

I think it would be interesting to the general practitioner branch of the profession to hear the opinions of men who have had extensive experience of coated pills.

Yours faithfully,

Shipdham, Norfolk, Sept. 14th, 1880.

IRVINE K. MILNE, M.D.

*Veritas.—*Though we do not agree with our correspondent's views, we might have been disposed to allow him to ventilate them in our columns; but the motives he imputes and the epithets he applies to the gentlemen respecting whom he writes make such a course quite impossible.

*Dr. Roderick Maclaren.—*The matter shall have attention.

THE LICENCE OF THE APOTHECARIES' COMPANY.

To the Editor of THE LANCET.

SIR,—As an old member of the profession, and one having a sincere regard for its position in the eyes of the public, I have read with much satisfaction the various articles that have lately appeared on this subject in the columns of THE LANCET, and trust that you will continue to uphold the view you have hitherto taken of the question.

It is impossible to doubt that the Apothecaries' Company as a licensing body is an anomaly and a superfluity. It is so in the eyes of the most intelligent members of the profession in this country, and in the eyes of foreigners it involves an absurdity, which they find it difficult to comprehend. As to the attempts made to explain away the relations of the licensing to the trading parts of the Company's affairs, they do not appear to me to be either very successful or very intelligible; for I suppose it will not be denied that a trade is still carried on by somebody at the Apothecaries' Hall, and that therefore the mere deputing of the licensing to other parties who use the name of the Company is something very like a subterfuge. But however this may be, the fact remains that the Company as a licensing body is a superfluity, and that if it retired from the scene, its place could at once be effectually supplied by the conjoint action of the Colleges of Physicians and Surgeons.

"Delenda est Carthago."

I am, Sir, yours &c.,

MEDICAL DEPARTMENT OF THE CONVICT SERVICE.

To the Editor of THE LANCET.

SIR,—Will you allow me to give a warning note to all who may be invited to accept employment in the Medical Department of the Convict Service.

Much as the Army and Navy Boards are to be condemned for their unwarrantable depreciation of, and enmity to, medical officers, the official mind that directs the affairs of prisons is invested with a thicker coating of prejudice than that which forms such a marked development in the heads of the other branches of the public service. Without the doctor the occupation of a prison governor would be at an end. Questions of every conceivable kind are submitted to the doctor's judgment from morning to night. The authorities know his value; but prejudice, or whatever the contemptible spirit is, forbids recognition of his worth. They place assistant-surgeons very nearly on an equality as to pay with a chief warder, and when promotion, which may be very slow, comes, the maximum pay never exceeds, and is often below, that of a deputy-governor, who may have been in the service only three months, and who easily acquired a knowledge of his duties in thirty minutes. As to treatment, *ex uno disce omnes*. An assistant-surgeon, who had been a distinguished scholar in his school, recently declined in health. Knowing that in two or three instances deputy governors had obtained leave of absence for long periods on sick certificate, he applied for a similar privilege, and offered to provide a substitute. The reply was on a level with the contumelious disposition of the authorities. He immediately received the notice, ordinarily given to subordinate officers and domestics, that he must go in a month, and that he would be recommended for a gratuity—probably a few pounds.

Let candidates, therefore, beware. They cannot join a more woful branch of the public service.

Yours obediently,

R. W.

THE BENGAL MEDICAL RETIRING FUND.

To the Editor of THE LANCET.

SIR,—Amongst the numerous discussions that have followed upon the recent amalgamation of the Royal with the Indian Medical Service, I have not observed any notice in your publication of the disastrous consequences of this change to expectant annuitants.

There are many men who, like myself, have been compelled from ill health to retire from the service on a smaller pension than they otherwise might have received. They, however, always had in view their Fund annuity, to which a compulsory subscription had been paid by them from their date of joining the service. The annuitants are appointed by seniority, and the periods after which the annuity has become available for retired men was, in 1877 and 1878, twenty-four and twenty-five years respectively. Last year, in consequence of the changes in the service, our seniors retired and took the annuities that, under the former conditions of the service, would have been allotted to us.

It is now upwards of twenty-six years since I entered the Bengal Medical Service, and there are retired officers still senior to me who now find their prospects of obtaining their annuity retarded for an indefinite period through this sudden and large influx of seniors to the retired list. In March last, in consequence of a representation of this grievance that I made in February, I received a communication to the effect that the same had been referred to the Government of India.

I cannot learn that any measures have yet been taken to compensate us for the postponement of the allotment of our annuities, although it must be well known that on the 1st of November next, the date on which the allotment always takes place, most of the eight annuities will be taken up by newly retired medical officers of twenty-eight years service and upwards.

Yours truly,

September, 1880.

BENGAL RETIRED.

AN ADVERTISING HOSPITAL IN BELFAST.

As hospitals cannot advertise themselves, it must be concluded that some individual medical man is responsible for the following piece of indelicate touting:—

"SAMARITAN HOSPITAL, BELFAST. — Objects: For the medical and surgical relief of women afflicted with diseases peculiar to the sex, including displacements of the womb, tumours of the womb and ovaries, ruptures of the bladder, strictures, blood-tumours of the pelvis, abscesses of the pelvis; the infirmities and diseases incidental to pregnancy, cancers of the breast and womb, difficult and painful menstruation, &c.; also, diseases of the bladder, piles, fistula, &c. Terms of admission for pay patients: 7s., 8s., 9s., and 12s. per week, according to accommodation desired or required. Free department: There is a free ward for those unable to pay. Out-patients seen daily at ten o'clock."

INTRA-PARIETAL TUBE.

Mr. H. G. Dyer.—Our correspondent's device, although ingenious, would, we fear, be attended with risk in its application.

Lecture
ON

AUDITORY VERTIGO.

Delivered at the National Hospital for the Epileptic and Paralysed.

By J. HUGHLINGS JACKSON, M.D., F.R.S., &c.

PHYSICIAN TO THE HOSPITAL.

WE are occasionally consulted by patients for attacks of vertigo. Sometimes the attack is epileptic, and then the case is infinitely serious; sometimes, at least many think so, it is owing to dyspepsia only, and then it is a thing of comparatively little gravity. Vertigo occurs occasionally as a result of sexual excesses. Some weakly people are giddy and totter if they get up quickly from the recumbent position, but here the attack, if we may call it one, is artificially produced. There is another kind of vertigo which has long been known, but which is not yet widely known—auditory vertigo, or, as it is often called, Menière's disease. It is quite certain that paroxysms of exceedingly severe vertigo occur with ear disease. No experienced person can deny that, even if he denies that there is a relation of cause and effect. Whilst auditory vertigo is the most distressing to the patient, epileptic vertigo is infinitely the most serious of all paroxysms of vertigo. Epileptic vertigo, I must tell you, is often used as a name for a very slight attack of epilepsy—for cases in which there is no true vertigo. I think it would be better to use it as a name for vertigo in slight epileptic paroxysms, or at the onset of severe ones. Thus, if a patient has, in a slight paroxysm of epilepsy, or at the onset of a severe one, the sensation of external objects moving, or of himself moving, I call that sensation epileptic vertigo. I do not call a very slight attack of epilepsy epileptic vertigo if there be neither of these sensations. In no case, indeed, do I conclude that a patient has vertigo unless I learn from him that objects appear to him to move, or that he feels to move.

The diagnosis of the nature of an attack of vertigo is not always easy. We ought to investigate the simpler cases first. There is a very important vertigo we have yet to mention; one, however, which does not come on in attacks; it comes on when the patient walks. I mean vertigo from paralysis of an ocular muscle, or of several ocular muscles. To study vertigo in cases of paralysis of ocular muscles is the most methodical way of beginning the study of vertiges in general. I think it is unwise to study auditory vertigo and epileptic vertigo before carefully investigating the much simpler case of vertigo from paralysis of ocular muscles.

Our subject to-day is auditory vertigo.¹ The term does not suggest the whole symptomatology of the affection it names, there is much more than giddiness with ear disease in a severe attack. The patient consults you for attacks of giddiness with vomiting, but the symptomatology is usually very much wider than this even. He will tell you that suddenly things seem to move—to move to one side, or to whirl round, or that he himself feels lifted up or pushed forwards. He is unsteady, and his gait is a reel, if walking be possible at all. Even when lying down he feels unsafe, and will grasp the sides of the couch. If he moves his head he is worse. The above vertigo, with reeling, is only one-half of the patient's condition. We may call the two symptoms we have mentioned locomotor symptoms. Vertigo is on the physical side incipient or rudimentary disorder of locomotion. The following additional symptoms we may call "vital." We see that the patient is pale and haggard, that there is profuse perspiration. He tells us that he feels sick, and he may vomit. He has horrible depression, he may say that he feels as if he were going to die, and not unfrequently com-

pares his condition to that in sea-sickness. Another symptom is pain in the head.

The paroxysm may last an hour or more. I have described what occurs in a severe attack; there are minor attacks, such as a little transitory giddiness and unsteadiness. There are also still severer attacks; sometimes the patient loses consciousness. A medical man told me that the first attack occurred in the streets in London. He was taken to a hospital unconscious, and remained so for three hours. Such a seizure would give us a hard task in diagnosis from epilepsy. Subsequently he had attacks without loss of consciousness.

In these cases there is "something wrong with the ear," or ears. Sometimes the patient has been long deaf of one ear before any attack; occasionally it happens that he is rendered deaf at his first attack; there is in other cases great noise in one ear when the paroxysm sets in, or an increase of a noise which exists betwixt the paroxysms.

In these cases the ear is the part in fault. But manifestly all the symptoms we spoke of as locomotor and vital are owing to something wrong with nervous centres. We may put it that the ear is in fault, and that the centres suffer. But this is not, I think, without qualification. Borrowing an idea from Sydney Ringer as to diminished resistance of centres in cases of migraine, I would suggest that any general lowering of health will be a factor in the production of auditory vertigo; the resistance of nervous centres being diminished, they more readily give way to the "irritations" by the ear. In another way of putting it we may say that the nervous centres are healthy in auditory vertigo, except, perhaps, for a defect in their nutrition in common with the rest of the body. They are, nevertheless, as healthy as any of the other centres, but they alone give way, they alone being worried *ab extra*. There is no reasonable doubt that the starting-point is ear disease; these particular paroxysms would not occur even in ill-health unless there were the particular defect ear disease. I find, however, that some patients consider the diagnosis to be nonsensical. A patient may reply that he has long been deaf, and that he does not care about his ear, that he does not come to you for *that*. (Sometimes, however, he does not know himself to be deaf of one ear.) He evidently supposes you are "thinking too curiously," that you are neglecting obvious causes and explaining the ailment by far-fetched and vague theoretical reasoning. The obvious cause to him is usually stomach and liver derangement; very naturally, for he vomits and may bring up much bile. He cannot see what an old aural affection has to do with a recent sudden paroxysm of vertigo, with urgent vomiting, and great prostration. He would be better satisfied, doubtless, by being told that his attack was due to "suppressed gout," to "liver derangement," &c., for these terms are familiar to him, if the explanations given in them are not really more intelligible. Then he may tell us, in confirmation of his hypothesis, that alterative aperients put him right again, not seeing that, the affection being in its nature transitory, he must come right after a time. What Buzzard says of treatment of batches of lightning pains in *tabes dorsalis* applies here.² I don't blame the patient, although I have to combat his notions. Not many years ago I did not know that ear disease was a cause of the symptoms I have mentioned, and I do not doubt in the least that my then erroneous, but quite conscientious, explanations appeared more rational to my patients than those I give now.³ You must not suppose that an advance in your knowledge of disease will necessarily make you more fitted to obtain your patient's confidence; it fits you to treat him better, and you must get your satisfaction out of that. If you tell a man who sees perfectly well that he has a grave condition of his optic nerves, he is often the reverse of being assured that you understand his case. The ophthalmoscopic examination which you make, simply because he has intense headache and perhaps vomiting, naturally seems to him quite irrelevant. If you told him that he was suffering from severe biliousness he might be satisfied. He may, indeed, reply to the expression of your opinion that he

² THE LANCET, Feb. 14th, 1880.

³ My attention was first thoroughly drawn to the subject by a masterly paper by Knapp, Archives of Ophthalmology and Otology, vol. ii., No. 1. I gave a short *résumé* of previous opinions on this disease, Med. Times and Gazette, Aug. 17th, 1872. Charcot has published one of the most important cases of Menière's disease. I have given an account of this in the Medical Record, April 22nd and 29th, 1874. A brief account of Menière's disease is given by Ramskill, in Reynolds's System of Medicine, the first account by a physician in the country, I believe.

knows it to be "all liver," and, perhaps, may add that he was always very bilious. One great thing you wish to do is to prevent his becoming blind, but if your iodide of potassium makes him "more bilious" very likely you do not see him again. In intense headache we should always use the ophthalmoscope, and if, as very often happens, you discover nothing wrong in a patient's eyes, he evidently feels that he scores one; he *knew* there was nothing wrong with his eyes. Similarly he often *knows* that there is nothing the matter with his heart, lungs, and kidneys, although we are obliged to examine the chest and urine as a matter of routine. If you get to know that hypermetropia is an occasional cause of severe head trouble, totally incapacitating the subject of it for study, you are in error if you suppose that a correct diagnosis founded on such knowledge will always be acceptable to the patient. Very naturally when he finds that, for a time at least, he can read small type, such an explanation of his symptoms appears to him simply absurd. Many of our patients seem to wish to have a conversation on their cases on some basis (gout, liver, rheumatism, &c.), which makes them feel that they follow the doctor in his investigations, and understand his conclusion. They cannot appreciate a scientific medical investigation. If a patient "who knows something of medical matters" consults you for amaurosis (simple optic atrophy), he naturally thinks you are wandering when, after looking into his eyes, you ask about pains in his legs, and then "tap his knees." If you took his view that the lightning pains in his legs were rheumatic, and that his failure of sight was owing to rheumatism of the optic nerves or their centres, he would be more in harmony with you.

Even medical men who have aural disease very often totally reject the proffered explanation of their attacks of vertigo; many of them also ascribe the ailment to digestive troubles. A medical man had deafness of his left ear, with occasional slight vertigo. One day, walking in his garden, he had pain in his head, was very giddy, fell in some shrubs, and vomited. This was plainly ear-vertigo, as he himself knew. But he had the following diagnoses made of his case by other medical men—(1) Nothing, (2) Nervousness, (3) Deranged stomach.

Be very careful how you interpret acute digestive symptoms. They may be effects, not causes. I imagine that in at least one in five cases of epilepsy the first paroxysm is erroneously put down to stomach derangement. Migraine, unquestionably a nervous affection, is very often similarly explained, and indeed goes under the unfortunate name of "sick headache." Besides, it is very common for cases of fatal brain disease to be explained away in their earliest stages as being caused in this simple manner. It is quite true that as we get older in practice we attach more and more importance to the state of our patient's alimentary system, for plainly our operations are often based on its condition. We always inquire now-a-days about our patient's digestion and regulate his diet, whatever ailment he may have, just as we examine his urine, heart, and arteries. But for my part I attach less and less importance to abnormal states of the digestive system as direct causes of definite nervous symptoms. Very often there is no other warrant for the diagnosis of liver affection in cases of intense headache, of vertigo, and of transient loss of consciousness, than sickness and vomiting, with the appearance, perhaps, of bile in the vomit. If anyone from any cause vomits long enough and strongly enough he will bring up bile; indeed, I should take a plentiful supply of bile in the vomit as evidence that the liver was working well. Vomiting is a very general symptom. I mean that it occurs under very many different circumstances—"shock," passage of a biliary or renal calculus, tubercular meningitis, tumour of the brain, migraine, ear disease; then there are the "gastric crises" of tabes dorsalis (Charcot). You do quite right, of course, to note the "stomach symptoms" in auditory vertigo, but you should inquire as to the state of digestion in the intervals of the attacks, when it is often quite good. When the digestion is right in the intervals the "dyspepsia" is paroxysmal, is part of the paroxysm, and no doubt depends on something wrong, not at the stomach end, but at or acting on the central end of the pneumogastric nerve. In a masterly article on "Vomiting in Connexion with Cerebral Disease,"⁴ Ferrier brings evidence to show that in cases of vomiting from cerebral or any other disease or morbid condition, irritation of the vagus, centrally or peripherally, is the one

thing in common to all. I think it is a good piece of work to make a comparative clinical study of the paroxysmal dyspeptic symptoms of migraine, auditory vertigo, and of those in some cases of tabes dorsalis ("gastric crises" of Charcot).

There is, however, described a "stomach vertigo," and as one of the describers of it is Trousseau, we must consider this matter with great respect. If you will read what Niemeyer calls Trousseau's "life-like description" of it, you will find that he does not really make out a strong case. He says that the attacks generally come on long after digestion, that sometimes a small quantity of food prevents an attack or stops it if it has begun, that stomach vertigo does not differ greatly from auditory vertigo, that the "slightest cause" may bring it on, as a sudden movement of the head, or looking at a range of bars, a trellised wall, or a striped pattern in the hangings of a room. I will read an extract from Niemeyer's well-known work. "As above mentioned, Trousseau believes that these attacks of dizziness depend on dyspepsia; at the same time he acknowledges that in many cases the signs of dyspepsia are so slight as to be readily overlooked. He relates cases of the successful treatment of 'vertige stomacale' by the alternate administration of infusion of quassia and a composition of carbonates of the alkalis. Even from this prescription I have never seen any benefit, and while I must acknowledge that the first attacks of dizziness affecting the patients that I have seen usually occurred after an indigestion, and were accompanied by dyspeptic symptoms, still in none of them were there evident signs of indigestion during the subsequent attacks, which often continued for years. I believe the repetition of the attacks of dizziness to be due to psychical causes." Observe how cautiously Niemeyer writes "usually occurred after an indigestion," and "were accompanied by dyspeptic symptoms"; he does not say "caused by." Curiously, some people deaf of one ear do not know it until it is pointed out to them. Hence Gowers has well said: "The fact that the patient may be unconscious of a most significant auditory defect lessens the value of former observations as evidence of the definite character of stomacal vertigo."⁵ I think Gowers will turn out to be right in what he has further written:—"My own conviction is that, in the vast majority of the cases in which a vertigo of definite and uniform character is apparently excited by gastric disturbance, an auditory defect will be discovered on careful examination." I confess that I do not believe that a sudden severe attack of giddiness would occur from dyspepsia, if there were not some flaw elsewhere. Of course, common sense leads us to treat dyspepsia whenever we meet with it; all would agree in this. But we must be careful lest we treat for it when it does not exist; and if there be dyspepsia, we must not neglect to care for other conditions which may not depend on the dyspepsia, or only very indirectly depend on it. I do not deny that ordinary dyspepsia, nor the dyspepsia artificially induced by over-indulgence, may be a factor. I think that dyspepsia, or any other cause of lowering of general health, is a factor in producing or allowing paroxysms both of migraine and auditory vertigo. This was in principle admitted when we referred to Sydney Ringer's opinions. Gowers has put the question very clearly:—"In persons the subjects of ordinary vertigo, whose equilibrium nerves and centres are damaged, a primary gastric disturbance seems sometimes to excite a paroxysm of the special vertigo to which they are liable, and the gastric disturbance which thus brings on the attack is naturally regarded as its only antecedent." An admirable observer, Dr. Russell of Birmingham, has described the case of a woman who had symptoms of gastric ulcer and paroxysm of "definite" vertigo, and no sort of ear affection; but he says that "some proclivity in one of the vaso-motor centres, or in some other part of the nervous tract involved, must be presupposed."⁶

To return to our special topic. No one need diagnose ear vertigo when there is nothing aural to get hold of. On any view, we should note the presence of ear trouble, if there be any, whether it is accepted as causative or not. This we are bound to do. If anyone believes that a patient's attacks of headache are really owing to deranged digestion, he is bound to take heed of any retinal projections there may be in the paroxysms (vibrating air, fortification outline, &c.), and of the mode of their progression over the field of vision. He has to hold his hypothesis, not by ignoring these

⁴ Brain, Part 6, July, 1879.

⁵ Brit. Med. Jour., April 7th, 1877.

⁶ Med. Times and Gazette, March 8th, 1879.

"definite" projections, but after fully considering them. Then, as Gowers points out, we have to note the kind of vertigo. To use again an expression of his, it is often "definite." Is it likely that when it is so particular that objects appear to be displaced to one side that stomach derangement is the cause of it? Is it not, on the contrary, more likely to be owing to some local lesion in the centres, even if not to disturbance of them by ear disease? And if there were no deafness, it would be rash to say there was no ear disease. I spoke also of retinal projections in some cases of migraine as being "definite." Is dyspepsia or any ailment affecting the nervous system generally likely to be the cause of a migraine with projections creeping over the field from one side towards the other? I entreat of you to inquire into the state of the ear in all cases of paroxysmal vertigo. I am ashamed to confess that I nearly made a very great diagnostic blunder recently by neglecting what I am now urging on you. Of course, you must not put down all paroxysmal affections, even starting with giddiness, as a matter of course to aural affection, even when there is such affection. Some attacks of epilepsy begin by noise in one ear;⁷ in some cases of epilepsy and of epileptiform seizures there is organic ear disease, and probably a causative relation. These two kinds of cases differ *toto cælo* from one another, and each also from cases of Menière's disease.

I will now recapitulate and also adduce further evidence showing the relation between ear disease and paroxysm, in which there is vertigo with vital symptoms, or in which there is ear disease with a slight and transient vertigo which is often definite. (1) There often is ear disease in the severest cases of vertigo. (2) Often the patient becomes deaf at his first seizure, and remains so afterwards. (3) When deaf of one ear (either before or after his first attack), suddenly turning the head in one direction may make him slightly giddy. (a) Thus one of my patients whose ear disease was right was a little giddy when he turned over to the left in bed. He had severe paroxysms also. (b) A medical man, whose ear disease is right, tells me in a letter, "The third attack was brought on by a sudden turn from right to left when lying in bed, when the giddiness and confusion lasted for eight or ten days. I have still difficulty in lying on the left side, and could still make myself giddy by turning quickly from right to left when lying. I can turn quite well any way when in the upright position. Auscultating with the right ear a patient lying in bed, the throwing the head to the right is apt to make me a little giddy, this does not occur when the head is thrown to the left." (c) Buzzard reports of a patient *subject to paroxysms of auditory vertigo*:⁸—

"The patient, deaf of the left ear and with noise in it, kept his bed three or four months, unable to turn his head to the left." These facts are, I believe, to be trusted. I must say, however, that the statements of patients as to side of body turned to or side affected in paroxysms of any kind are not to be confidently relied upon. (4) Some patients deaf and subject to attacks may make themselves a little giddy by pressure on the ear. Schwabach reports a case of discharge from the left ear, in which pressure above and below the left auricle caused the eyes to oscillate horizontally to the left side, and slightly downwards—that is to say, the pressure produced a physical condition for vertigo; moreover, the patient felt giddy. I take the following from a paper by Maas:⁹ "Of late E. Pflüger observed a case of formation of polypi on the posterior wall of the external auditory canal, close to the membrana tympani. When the polypi were touched with a probe, oscillatory movements in the horizontal direction ensued in both eyeballs." Flourens and other physiologists give oscillation of the eyeballs as one result of experimental injury of the semicircular canals. (5) Syringing the ear in some patients with aural disease produces an attack of auditory vertigo. Every medical man has seen patients thus treated ghastly pale, and reeling. In Schwabach's patient the oscillatory movements of the eyes were repeated in a lesser degree on syringing the ear. (6) Some foreign bodies in the ear produce great misery. I do not know, however, that they produce paroxysms like those of Menière's disease. You are aware that the pneumogastric

nerve sends a branch to the membrana tympani—some say to enable us to hear the dinner-bell. The membrana tympani receives branches from the fifth also. Possibly irritation of the pneumogastric branch is in greatest measure to blame for such symptoms as occurred in the following case. The case is of some interest; possibly it is a very common one in aural practice. For the notes of it I am indebted to Mr. Lewis Mackenzie, formerly house-physician at the London Hospital:—

About 12.30 P.M. on Dec. 30th, 1872, John D—, aged twenty-two, a strong-built soldier, came into the receiving-room of this hospital in a state of great mental excitement. His face was much congested, the conjunctivæ were suffused, and for the moment it seemed as if he were the subject of a delirium from drink. He was complaining in an excited manner of a "buzzing" in the right ear, and of intense pain, the character of which he could not describe. He frequently repeated that "he would go mad if not relieved." His head rested with his right ear on the palm of his right hand, and it was noticed that he frequently walked round and round, and always from right to left. The house-surgeon had some difficulty in getting him to be quiet, and explain his sufferings. When asked how long he had had the pain, he said since he got out of bed in the morning; in fact he awoke in great pain, "The pain woke me, but has got worse and worse." Whilst I was deliberating as to the diagnosis, the patient said, "It feels like a large insect in my ear." This leading observation at once suggested an examination of the ear. Nothing was seen by ordinary examination, but with an ear speculum and reflected light from a mirror all the tissues appeared healthy, but on more close examination a small black dot was seen at the anterior wall of the tympanum and its junction with the mucous membrane of the external ear, and moving about as if trying to scratch its way between the membrana tympani and the wall of the meatus. One syringeful of water brought out the offender, which proved to be a louse of rather large size, and dark. The patient was *at once relieved*, though his ear still felt "queer." He left the hospital in a state of intense gratitude.

(7) There are the well-known experiments of Flourens on the semicircular canals, narrated in every text-book of physiology. (8) There are the recent inestimable experiments of Cyon, carrying us a long way further than those of Flourens. (9) There are the researches of Mach and Crum Brown into the functions of the semicircular canals; these researches are of great value; by showing the particular importance of these canals in health they indirectly enforce the opinion that diseases of them may produce definite locomotor symptoms; they are also most valuable contributions to the physiology of the nervous system.

My chief subject is the paroxysm, but there are "chronic" cases. I speak of these to enforce that vertigo and reeling may have a causative relation with ear disease, that not only do "attacks" of vertigo go with it, but that more continuous vertigo does also; in some cases there are both attacks and frequent or continuous reeling. Of course, there is another difference between the two than that of acuteness and chronicity, which, however, for our present empirical purpose, does not concern us. A few persons with ear disease nearly always, or for very long periods, walk unsteadily; they have to walk with attention, and sometimes with their legs too widely apart; they feel slightly giddy; they may walk as if slightly drunk. If the deaf patient comes to you walking well, and yet complains that he frequently is unsteady, you should get him to walk a short distance with closed eyes. All sorts of bad walkings are made worse by closing the eyes, although none so much worse as the gait in locomotor ataxy. I will mention only one case of this kind. I have recorded it in *Brain*, Part 5, vol. ii., April, 1879, partly from notes by Mr. Lewis Mackenzie. It looks to me like a production of chronic vertigo and reeling by experimental injury of one ear. A medical man, after firing a heavily-loaded gun, felt giddy and stunned, and walked badly. Since he has been partly deaf of the right ear, has had noise in it, and has tended to the left side in walking; when arm in arm with someone he would pull or push his companion to the left, according to the arm hooked to. His wife had often to remind him that he walked to the left. He is never without the noise in the right ear. This case is, so to speak, the production of "half a reel" by injury of one ear.

In the case last mentioned there were no paroxysms, but, as already said, there are cases with both severe paroxysms

⁷ I have published two cases of this kind without autopsy in THE LANCET of March 11th, 1876, p. 338. Recently I have, as Gowers mentions in his second Gulstonian Lecture (THE LANCET, March 20th, 1880, p. 435), had an autopsy in a case of epilepsy, or epileptiform convulsions, in which noise in one ear was the "aura." Gowers examined the specimen for me, and found tumours in the opposite side of the brain.

⁸ Clinical Society, THE LANCET, March 4th, 1876.

⁹ Archives of Ophthalmology and Otology, vol. vii., p. 493.

and interparoxysmal slight symptoms. Some patients have strong paroxysms and frequent slight ones. A patient, under the care of my colleague, Dr. Buzzard, besides having strong paroxysms, has what he calls "staggers" five or six times a day, or even in an hour. He has a feeling of sickness when they come on.

So far we have only empirical evidence of various kinds to show that there is a relation betwixt ear disease and certain nervous symptoms. That there should be is a necessary outcome of very old physiological researches on animals, and of the very recent ones of Cyon.

Lectures

ON

THE RELATIONS OF SARCOMA TO CARCINOMA.

Delivered at the Royal College of Surgeons in June, 1880,

By HENRY TRENTHAM BUTLIN, F.R.C.S.,

ERASMUS WILSON PROFESSOR OF PATHOLOGY TO THE COLLEGE, ASSISTANT-SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, &c.

LECTURE II.—PART II.

SUBPERIOSTEAL TUMOURS OF BONE.

LET us pause for a moment to consider the characters which all these tumours of the femur bear in common. First, their deadly nature and rapid course. Eighteen are dead, and, of the remaining three, only of one is it recorded that he was still alive a year after amputation. But of the eighteen who died, five lost their lives from the direct effects of operation. The operation was practised so early in three of these cases that we are not surprised the autopsies showed no affection of the viscera. The nine post-mortem examinations of other cases revealed affection of the lungs in all. And of those on whom no section was permitted, more than one died with well-marked signs of pulmonary disease. Affection of the glands occurred so rarely that it is more difficult to explain why the glands were sarcomatous than why they were not. But as I think the explanation may more easily be given during or after the discussion of the tumours of other bones, I shall defer it until then. Affection of more than a single organ occurred only in the round-celled sarcomas. Recurrence of the primary disease was rare. Ossification, calcification, chondrification, were so common that they were present in almost half the cases, and with these changes softening down into cystoid spaces, sometimes with the formation of a locular structure, was often associated. Ulceration of the integuments was almost unknown; even those tumours which were permitted to pursue their course without interruption to death did not break through the skin. The duration of disease was in most cases from nine to twelve or fourteen months, but two died with affection of the viscera within four months, and one lived for three years. Of the age at which these tumours of the femur grew, I can only say that they were rare before the age of puberty, were still more rare after forty, and were most frequent from twelve to thirty years of age. In connexion with this point let me call attention to an arithmetical fallacy into which Prof. Gross has been betrayed, and into which, therefore, others may also be misled. In describing each form of sarcoma he has taken the mean of the ages of a number of patients, and has assumed that this mean represents the age at which the disease will be most frequently observed; but the mean of ages does not necessarily correspond with the age at which the disease most frequently occurs. If, for example, we take the mean of the ages of these patients with spindle-celled tumours, it is found to be 24·3; but there are only two patients whose age is within three years of this mean age, while all the others are either younger than twenty or older than thirty. Again, the mean age of those with mixed-celled tumours is 23·1. But five of the eight patients are under sixteen, or over thirty years of age. So little does the mean age of these cases represent the real age of occurrence.

Of size, or shape, or contour, little can be said. Large

size, fusiform shape, smooth contour, were perhaps the properties most common. But of position there can be no question; the lower end of the bone, and next to this the diaphysis, had the preference. Last of all, the disease may be traced to blow or squeeze in some few instances; one of these I have already mentioned.

The tumours of the TIBIA include all three varieties, but the spindle-celled is represented by a single case. This patient and one other died without operation. In both the skin was ulcerated; in neither was there visceral disease. In no important respect do the three varieties differ among themselves, save in the prevalence of ossification or calcification in the mixed forms, but in some respects they differ widely from the tumours of the femur. Thus two of them occurred in patients over fifty years of age; in only one instance is there clear history of hurt; growth is often slower, the tumour not infrequently breaks through the skin and fungates, and the whole course of the disease is milder and less markedly malignant. Thus the round-celled tumour of No. 22 had already existed for many years before the thigh was amputated. Two years later a tumour appeared in the calf of his other leg, and grew rapidly. The symptoms of cachexy were already far advanced when this tumour was removed, and in three weeks death followed the operation, caused not by the operation, but by the continuance of the cachectic symptoms. No autopsy was made, therefore the supposition of lung disease, to which the symptoms distinctly pointed, could not be verified. It may be doubted whether these tumours were not separate outbreaks of tumour-disease, bearing no direct relation to each other, but each bearing a like relation to a disposition in the patient to the formation of such tumours. The second tumour was much softer and more juicy than the first. Another of the patients with round-celled growth was well sixteen months after amputation through the thigh. In this case and in two of those who suffered amputation for mixed-celled tumours (Nos. 27 and 28), the operation appears to have delayed or even arrested the course of the disease. One of these was a young mason, twenty years of age, whose tumour, as large as his head, grew from the upper portion of the tibia. It formed an aggregate of partly isolated, partly confluent lobes of what looked like pale golden spongy bone; around the lobes was softer brain-like substance. The microscope, however, showed a deposit of earthy salts, not true bone. The thigh was amputated when the tumour had existed seven months, and two years later the patient was alive and well. The other was a youth of eighteen years, whose leg was amputated by Mr. Croft seven months after the lower end of the tibia had been the seat of a large soft and pulsating tumour. It had the consistence of firm brain, possessed a ruddy hue, and exhibited a reticulated structure, of which the trabeculae contained bone, the meshes, soft cell growth. Nearly a year after the operation the hip was amputated for a soft and spongy tumour of the femur, first noticed four months after the removal of the leg; and with this tumour was removed a group of glands whose size and colour left no doubt that they too were sarcomatous.

It should be observed that this is the only tumour of the tibia with which was associated glandular disease; and in this case I cannot but think it far more probable that the affection of the glands was due not to the tumour of the tibia, but to the tumour of the femur. The skin in this case and in another somewhat similar was broken. It may therefore be supposed the ulcer thus formed established a drain, through which the course of the disease was averted from more vital parts. Or, to express this in other terms, the pressure within the tumour was relieved by the breaking of its surface, and with the relief of pressure the tendency diminished to the projection of cells or fluids into the vascular and lymphatic channels. If it be really true that ulcerated sarcomas are less liable than others to dissemination, the very faculty of ulceration possessed by tumours of the tibia may be regarded as a sign of less malignancy.

That sarcoma of the tibia may affect more vital parts is proved by the autopsy of one case in which secondary growths filled the lungs, is indicated by the well-marked signs which were present in other cases. The seat of election of sarcoma of the tibia in two-thirds of these cases was the upper end or upper third, in which respect, again, the tibia differs widely from the femur.

Like the tibia, the FIBULA is most often affected at the upper end—indeed, of these two tumours, both occupied the upper third or upper end. The mixed-celled tumour differs from the other, first in its calcification, in which it

corresponds with the mixed-celled tumours of other bones, next and more important in the manner of its generalisation, for the secondary growths occurred, one in the other calf, many in the subcutaneous tissue, but none in the viscera. In other respects their histories are parallel—the age, the position of the tumour, the rapidity of growth, invasion of the surrounding muscles, absence of lymphatic affection, death within a year, in neither case due to amputation, but in each case in spite of amputation from the continued progress of the disease. No autopsy was obtained of No. 31, for he died at home in Wales a few days after his return there from the hospital, but the supposition is strongly in favour of affection of the lungs, the signs of which were present before and after amputation in a continued shortness of breath and frequent hacking cough, both of which increased in severity until he died.

Of tumours of the HUMERUS I have but five cases, four of which are round-celled, and one spindle-celled. But few as are the instances, certain of the features which they exhibit in common are so marked and singular that they may well be borne in mind. All five grew on the shaft of the humerus; all grew with a surprising rapidity; all grew along the shaft of the bone, yet through the periosteum, which therefore could not long have confined them, into the surrounding muscles. As an example, I cannot adduce a better than that of a child six years old (No. 36), who had been always well and strong until the beginning of the present year. There then appeared in the middle of his right arm a lump of small size lying deep down upon the bone, owing no cause, producing no pain, and giving rise to so little inconvenience that it was regarded by the parents as an ill of minor kind. But it spread with fearful speed, so that in less than five weeks it occupied the whole arm, from the elbow to just below the shoulder. The skin was red and hot, the forearm swollen and œdematous, the tumour so soft and elastic as almost to fluctuate. A section after amputation at the shoulder-joint displayed the whole diaphysis surrounded by a brain-like growth, through the midst of which the periosteum could be traced raised from the bone like the arch of a bow. The bone was softened so that it could easily be cut or broken. The tumour extended through the muscles almost to the subcutaneous tissue.

That these tumours are exceedingly malignant may be inferred from the rapidity and manner of their growth, yet none of them produced enlargement of the glands. Two recurred after amputation—a circumstance easily explained by their position, and by their extension into the surrounding muscles. Two died from the effects of the operation; but although there are three deaths only one autopsy is recorded. In this case the lungs were the only viscera affected.

The forearm presents us with a solitary case—a calcifying, mixed-celled tumour of the ULNA, growing from its upper third, but occupying the bend of the elbow and lower part of the arm. A series of five smaller tumours extended up the arm, in the substance of the biceps muscle, but the axilla was free from disease, and remained so till the patient's death. The tumour was noticed in February, 1869, and the limb was amputated in February, 1870; but within a month he was attacked with paraplegia, and the cough which had been noted at the time of operation became more urgent. Towards the end of March he died, but no autopsy could be obtained.

Of the CLAVICLE there are two cases, both round-celled, both in males, both in young subjects. Nor does the resemblance cease here, for the growth of both was rapid. In both the neighbouring glands appeared to be affected; in one certainly, for some of them were removed when the tumour, with the affected portion of the clavicle, was resected; in the other probably, yet not so surely, for in the recurrence which took place the irregular growth might well have been mistaken for glandular enlargement. In both the surrounding soft parts were involved in the disease; in both the tumour bore the same opaque-white colour and cancerous appearance. The cases are distinguished by the difference in the position of the tumours, the one being attached to the sternal, the other to the acromial, half of the bone; and in the rapidity of their growth, for to attain its size, in which it scarcely doubled the lesser, the tumour of the older patient had occupied six times as long. I am not able to give the date of death, and therefore the total duration in either case; for of one the termination is unknown, and of the other, although his death was ascertained, it took place in a remote region of Ireland, whence I could obtain no further information respecting him.

The three tumours of the LOWER JAW are all spindle-celled, all of female subjects, of the body of the jaw, of rapid growth. Unfortunately neither case is complete, No. 42 least of all, for its history is traced only up to and immediately beyond the operation. Of the first two each is known to have died with recurrence of the disease, although resection was practised in one of them, two, in the other three months, after the first appearance of the tumour. Recurrence took place almost from the time of the operation in the former, only after seven months in the latter, a difference for which we yet may find a reason in the muscle-invasion recorded in the first. No post-mortem examination was made in either case, but the glands appear to have been sound. It remains only to be said that of these three cases one was chondrifying.

The sarcoma of the RIBS is chiefly interesting for the rarity of primary sarcoma of the ribs. It deserves attention, too, for that it attacked two ribs close to their heads, destroyed much of their structure where it grew from them, possessed no capsule, infiltrated the surrounding muscles, was excised at the end of a year, and left the patient alive, free from recurrence, and with all the signs of health nine months after operation. We have seen from one of the cases of the lower jaw how widely different may be the course of a chondrifying spindle-celled sarcoma, even when, as in this instance, its bulk is mainly made of cartilage.

The rapidity of growth and quick recurrence of the one contrasts strangely with the slower growth and the effect of operation in the other. How can facts so much at variance as these be reconciled?

Yet, I think, perhaps some explanation may be found—first, of the different speed of growth in the different conditions of moisture and vascularity and power of resistance of the affected parts; next, of the difference as regards recurrence in the relative freedom with which removal can be effected of a tumour of the jaw, and of a tumour of the back.

I have already said that probably I should have collected a greater number of tumours of the PELVIS were it not for the difficulty in deciding their origin. This applies especially to tumours of the sacral region. Even these three cases, however, furnish some points in common which well may serve to illustrate not only their pathology but that of all subperiosteal tumours. They are all round-celled, all of males, all growing from the innominate bone, and of course all fatal. But in one important respect two of them differ from the third, and also from most of the tumours I have hitherto discussed, I mean in their infection of the lymphatic glands. In order rightly to appreciate the importance of this circumstance it must be studied in connexion with certain facts in which these tumours differ, and with some facts in which they both agree. Observe, on the one hand, that there was sixteen years difference in age between these two patients, and one of the tumours was a simple round-celled tumour with bands of fibrous tissue, the other a chondrifying sarcoma, therefore these things are not the cause or the prevention of glandular affection. On the other hand, both these tumours were of enormous size, were without capsule, grew into the surrounding muscles, filled a large part of the cavity of the pelvis, and were therefore brought directly in contact with, and probably grew into, the lymphatic glands. These characters of concordance and disparity would be of less moment were they not so strongly contrasted in the remaining tumour. The very points in which it agrees with one of them are those in which they differ from each other; the very points in which it differs from them both are those in which they most agree. Even the pulsation of the second and third and its absence in the first, and the short duration of the first and second compared with the slow course of the third, may be adduced as evidence in favour of the argument. Of No. 46 it must be stated that although the patient died from the effects of operation the lungs were already full of secondary growths.

The bones of the SKULL are subject to all three forms of sarcoma—to neither of the three forms apparently in marked pre-eminence. From whatever region of the skull they grow, whether from the vault or from the base, there is entire absence of glandular affection, unless that be considered glandular affection which, except that by it certain glands are affected, differs in no way from generalisation by the blood. I mean the affection of glands which lie far distant from the primary disease—not even in the line between it and the main lymphatic trunk.

As examples of such affection let me adduce two cases of

round-celled sarcoma (Nos. 48 and 49), which deserve on other grounds a more extended notice. They are both cases of what has been called chloroma or green cancer, a rare disease, said to have been described first by Balfour, now five-and-forty years ago. Even at the present time there exist so few recorded cases that they may be counted by units. Yet the disease bears characters that can scarce be overlooked. It commences in the bones of the skull or face, is of periosteal or subperiosteal origin, produces always or almost always multiple tumours of the skull, runs a most rapid course, producing growths of unconnected and unexpected parts, such as the bronchial and mesenteric glands, the kidneys, prostate, testes, breasts, and lungs, and kills in from three to six months. All the growths, wherever they occur, present a similar green colour and round-celled structure. Thus much at least is gleaned from the recorded cases, which have been well analysed by Huber, who, in 1878, was able to collect but seven of them.¹

In some features, which distinguish them from tumours of almost every other bone, these chloromas differ not at all from most sarcomas of the skull. Multiplicity, for instance, is so common that most sarcomas of the vault present, not one, but many flattened tumours of the inner or the outer table, and this equally whether they are mixed-, or round-, or spindle-celled. They grow, too, as if simultaneously, upon both aspects of the bone, so that it is rare to find a tumour of even moderate bulk upon the outer, which has not its counterpart, although perhaps not quite of equal size, upon the inner surface. Yet this occurrence is not, as I believe, due to simultaneous growth, but to penetration of the bone either from the inner or the outer side. The direction of growth of any tumour is determined mainly by two factors: first, the resistance offered by the surrounding parts; and next, their capacity for contagion by the tumour elements. The resistance offered by the tight-drawn pericranium on the convex aspect, and by the dura mater within—to which must be added the intra-cranial pressure—must in every case be great; neither of these membranes is easily infiltrated or destroyed by the disease. But the bone yields readily before the invading host of cells; its surface is eroded, its cancellous tissue filled with the new material. Its Haversian canals are widened and varicose, its cancellous spaces enlarged, and all these parts are filled with a similar tissue to that which formed the tumours. Probably, too, the infiltration of the substance of the long bones at the seat of sarcomas of superficial origin, which is rarely, if ever, absent, is only another example of the effect of similar forces.

Frequent as are tumours of the inner aspect of the bone, death from pressure on the brain is rare. While the greater part, at least, of tumours of the skull cause death within a year or little more, some of them are marked by a much slower growth and longer course. Of this the most characteristic example is a spindle-celled sarcoma of the forehead and head of a young man, nineteen years of age (No. 52), which had grown gradually until it attained a large size and helmet shape. It extended from the eyebrows to behind the parietal protuberances, and across the vault from one semicircular line to the other. Its contour was smooth, its consistence firm and elastic. After two years and a half the patient died, not from the growth or generalisation of the tumour, but four days after an unsuccessful attempt by Von Rothmund to remove it. It is hardly to be wondered that the attempt failed, for, on section, the mass penetrated the bone through a series of fine pores, and was even grown into the cavum cranii on either side the falx cerebri as a tumour, the size of a hen's egg. Yet the patient had betrayed no signs of derangement of the functions of the brain, if we except a slight occasional sensation of giddiness. In its minute structure the tumour consisted merely of closely-massed spindle-cells, varied by the presence in its deeper parts of stalactite processes growing into it from the surface of the bone.

No secondary deposits were discovered in the body. Only in the absence of myeloid cells does this tumour differ from that so admirably described by Sir James Paget in his lectures on Tumours.² The duration, position, manner of growth, even to the projection on either side the falx cerebri, are the same in both. And in that case, as in the one I have just recorded, there were no growths in any other part of the body. The long duration and slow malignancy of these

cases is the more remarkable that they have no parallel in the spindle-celled tumours here collected of other bones, and are totally unlike the other spindle tumours of the skull. Nor can they justly be compared with these two mixed tumours of the skull, both of which existed an almost equal time, and neither of which appears to have been generalised. For the structure of these tumours differs so much from that of other mixed-celled tumours that I have been in doubt whether these are in truth sarcomata. Each of them was composed largely of fibrous tissue, mixed with cells of various shapes, sometimes collected in irregular spaces. The tumours of the base grew in each case from the body of the sphenoid bone, and differed only in one important respect from those of the vault, that neither of them was multiple.]

CASE OF MALFORMATION OF THE HEART.

By THOS. B. PEACOCK, M.D., F.R.C.P.

Great constriction or stenosis of the orifice of the pulmonary artery; aorta arising from both ventricles; defects in the fold of the foramen ovale; ductus arteriosus closed.—The child which was the subject of this malformation was first seen by me at St. Thomas's Hospital in the spring of 1876. It was then a year and seven months old, and the signs of malformation of the heart were very marked. The lips, hands, and feet were very livid, the ends of the fingers and toes were clubbed, and the nails incurvated. The cyanosis was probably present from birth, but it first attracted decided attention when the child was nine days old. It had gradually become more marked since that time. The head was disproportionately large, and there was some inequality between the two sides. The jugular veins were greatly distended, and there was a systolic murmur heard in the region of the heart. The scrotum and inguinal regions were very livid and in places excoriated. The temperature in the axilla was 98°·6°, that of the ward being 57°. The child was stated to be very easily chilled, so that it required to be very carefully protected against the cold. Its digestion was also very difficult, and great attention was needed in feeding it, and when the food did not agree, the breathing became difficult, and there was violent beating at the heart, and increased lividity. On August 25th, 1876, the child was again seen by me at my own house. The eruption on the skin had subsided under the use of warm baths, but the cyanosis was very marked. There was a loud systolic murmur in the pulmonary artery, which was not heard in the course of the aorta, nor at the apex. The temperature in the axilla was 97°·2°, in the hand 92°·6°, that of the room being 65°. After this time I did not see the child again till the commencement of its last illness in August of the present year. In the interval it had passed favourably through measles and whooping-cough, and had had attacks of croup and of jaundice.

The last illness of the child commenced on August 8th with earache and restlessness, followed by loss of power in the right hand. In the afternoon of the 9th he had violent shaking of the right arm and hand, and the following morning of the right leg also, with twitching of the right side of the face, and the right arm and leg were powerless afterwards. On the evening of the 12th the temperature was 101°; on the 22nd he had a general convulsive fit, followed by partial stupor; on the 23rd he recovered consciousness and could speak, though he did not articulate distinctly; on the 24th he had a second attack of convulsions, after which he was entirely unconscious, and he gradually sank till he died, at 11 P.M. on the same day. He was six years and nine days old at the time of death. During the child's illness it was attended by Dr. Bateman and Dr. Glover of Islington.

The post-mortem examination took place at the child's residence on the 27th, and was made by Mr. King, the senior clinical assistant at the Victoria-park Hospital, in the presence of Dr. Glover and myself. There was much difficulty in obtaining permission to examine the body, and the examination was restricted to the heart. The organ was of large size for the age of the subject; it weighed four ounces and three-quarters avoirdupois. From the heat of the weather and the time which had elapsed since death, the organ was very flaccid. The aorta was

¹ Archiv d. Heilkunde, 1878, xix., 8. 129.

² Lectures on Surgical Pathology, 1863, vol. ii., p. 221.

situated further to the right than usual, and the ascending portion was of large size. The pulmonary artery, on the contrary, was very small, and its coats thin, like those of a vein. The orifice was very small, admitting only of the passage of a cylinder measuring seven Paris lines (15·75 mm.) in circumference. There was only one valve at the orifice, and that was much thickened. The ventricles, but especially the right, were large, and their walls thick. The septum of the ventricles was deficient at the upper part, so that the aorta communicated with both cavities. The right auricle was very much dilated. The foramen ovale was closed, but there were several large openings in the fold. The ductus arteriosus was impervious.

The malformation of the heart in which the pulmonary artery is constricted and the septum of the ventricles defective, so that the aorta communicates with both ventricles, of which this case affords an instance, was first described by Sandifoot in 1777, and a considerable number of cases of the kind have since been placed on record in this country, France, Germany, and the United States. Indeed, as stated by Dr. Farre in 1814, it is the most common kind of deviation from the natural conformation of the heart. I have myself described four cases, and in 1866 I had no difficulty in collecting references to upwards of sixty published cases. When the child was first seen at St. Thomas's Hospital, from there being a loud murmur in the course of the pulmonary artery, it was thought most probable that it was a case of pulmonary stenosis, and as in cases where the pulmonary artery or its orifice is much constricted there is generally imperfection in the septum of the ventricles, it was supposed that the case was one of the combined form of defect. During the last illness, however, the murmur at the heart did not exist, and no precise diagnosis could therefore be formed, though it was thought most probable that it would prove to be a case of pulmonary stenosis with an aperture in the intraventricular septum.

The duration of life in cases of this description varies considerably, being mainly influenced by the degree of impediment to the circulation resulting from the cardiac defect.

In my own cases the patients survived to the ages of two years and five months, six years and a half, nine years, and nineteen years, death being in the last instance due to choleraic diarrhoea during the cholera epidemic in 1854. Of 45 published cases, 5 proved fatal under three years of age, 13 between three and seven, 12 between seven and twelve, 7 between twelve and eighteen; 2 lived to the age of twenty-one, 1 to twenty-two, 1 to twenty-three, 3 to twenty-five, and 1 to thirty-nine.

The death of the patients is, in the largest proportion of these cases, as in the present instance, caused by cerebral disease. Two of my previously published cases died in attacks of convulsions. It would have been interesting to have ascertained the precise seat and nature of the brain disease in the case, but permission was with difficulty obtained for the examination of the body, and examination of the heart only was allowed.

Though during life the temperature, as in such cases generally, was below the average, it will be seen that it rose during the child's last illness to 101°. In a cyanotic child, whose case is reported in the Pathological Transactions, the temperature rose during a fatal attack of measles to 104°.

HEMIANÆSTHESIA REMOVED BY STATIC ELECTRICITY.

By PROFESSOR B. BALL.

M—, aged nineteen, entered the Laennec Hospital, Paris, on January 25th, 1880. Family history: father died from the effects of an accident; mother living, nervous, and of strange and fanciful character. One brother died, in infancy, of convulsions, and another of a complaint unknown.

The patient herself has lived in Paris for the last five years. She has menstruated since the age of sixteen, but irregularly. Ten months since the catamenia disappeared after a prolonged exposure of the feet in cold water. A hoarse, barking cough supervened and has not yet ceased.

In March, 1874, her mistress amused herself by "magnetising" her, and this practice has been continued daily. Som-

nambolic sleep was easily induced. The patient says that she could put herself to sleep by joining her hands and exerting her will. The first hysterical attack took place on Jan. 10th, 1880, when she had two fits. On the 23rd, two more, which were violent and prolonged. The 24th, a slight attack. The menses had appeared on the 22nd.

Jan. 25th.—On admission the patient presents every appearance of health. She is well developed, strong and fresh-coloured. Her general condition is excellent. She was found to be completely anæsthetic on the right side, but of this she had previously been ignorant. Hearing, smelling, and taste are manifestly weakened on this side. Vision appears to be equally good on both sides, but no tests were applied as regards achromatopsia. There is slight ovarian hyperæsthesia on the right side.

28th.—Some choreic movements occurred on the right side.

29th.—Patient had an attack which lasted a quarter of an hour.

30th.—Patient nervous and excitable. Under the influence of slight pressure on the right ovarian region a violent attack took place, which lasted for ten minutes. She had no recollection of it afterwards. A mixture was ordered containing bromides of ammonium and sodium, three grammes of each daily.

From this date attacks occurred frequently; sometimes at a few days' interval, and there were occasionally several on the same day. During the attacks there is always laryngeal spasm, with hissing inspiration, and there is always headache afterwards, which sometimes persists until the next attack. At first the hysterical fit could be arrested by pressure on the right ovary, but after a time this became ineffective, and the inhalation of chloroform was substituted. This soon lost its action, and only suspended the attack, which would take place as soon as the inhalation was over.

From March 8th various modes of treatment were adopted, including "hydropathy," chloral, tartar emetic and morphia, and also continuous and faradaic currents. No improvement was observed in the patient's state with the exception of a few hours sleep at night. The hemianæsthesia and choreic movements still persisted, and as a natural consequence the limbs exhibited numerous bruises. It was then proposed to adopt static electricity as a method of treatment, the other modes of applying that agent having entirely failed. On July 30th the patient was placed upon an insulating stool with glass legs, and submitted for twenty minutes to the influence of the negative fluid of Nairn's static electrical machine. The experiment was abruptly brought to a close by the patient falling to the ground. When she rose the anæsthesia had completely disappeared. Sensibility was tested by the æsthesiometer and a variety of other means, and found to be perfect. There was no *transfert* in this case, the left side retaining its previous degree of sensibility. The sense of touch, however, was slightly more acute on the right (previously anæsthetic) side than on the left. Before the experiment the prick of a pin did not draw blood from the right arm; immediately after the prick of a pin drew blood. The plantar-reflex was the same on both sides, the choreic movements were lessened, and locomotion had become much easier.

The improvement thus acquired continued for a whole month, and on August 6th the catamenia reappeared. Up to the beginning of the present month (September) the girl remained in a satisfactory condition, but after that period she gradually began to lose ground, and has now relapsed into her former condition. It is proposed to commence the treatment by static electricity within a few days.

The noteworthy features of this case are: 1st, the sudden recovery of sensibility in consequence of a single application of static electricity, when everything else had failed; 2nd, the absence of *transfert*, both sides remaining in the normal condition; 3rd, the recurrence of the former symptoms after an interval of a whole month, during which the patient enjoyed perfect health.

It will be interesting to watch the further progress of the case, but as the facts now stand, they seem fully to justify the employment of static electricity in cases of hysteria, with or without hemianæsthesia.

Paris.

THE foundation-stone of a new chapel for the Bristol Borough Lunatic Asylum was laid on the 24th ult., in the presence of the Mayor and Mayoress and the visitors of the asylum.

FIVE YEARS' SURGICAL WORK IN THE
CARDIFF INFIRMARY.BY ALFRED SHEEN, M.D.,
SURGEON TO THE INFIRMARY.

IN 1874 Mr. Edward Lund, one of the surgeons to the Manchester Royal Infirmary, published the results of five years' surgical work in that institution, based on a record of 1309 cases, to illustrate the utility of following out some "ready method of recording surgical cases in hospital practice," and as an inducement to other surgeons occupying similar positions in connexion with such charitable institutions, to undertake a similar task, "and thus by comparing different modes of treatment in those cases which form the routine of every-day surgery, to render our practice more correct and more certain in its results." As one of the two honorary surgeons attached to a small county infirmary making up a total of 58 beds, I have endeavoured to carry out the plan initiated by Mr. Lund, and, in doing so, I have availed myself of his admirable suggestions for a "ready method of recording cases in hospital practice." The following paper is the outcome.

During the period traversed by these notes (1875-79) I have had a total of 682 cases under my care—viz., 367 injuries and 316 diseases. My arrangement of these cases is somewhat different from that adopted by Mr. Lund. I have divided them first into two great classes—injuries and diseases; and in the latter, instead of referring the cases to the various parts of the body, I have, for the most part, placed them in classes which indicate the structure diseased. In addition, I have dealt separately with the various amputations and operations rendered necessary by the nature of the accident or disease for which they were performed. According to this arrangement the cases may be tabulated as follows:—

A. Injuries.

1. Contusions	60
2. Sprains	19
3. Wounds	88
4. Burns and Scalds..	20
5. Dislocations	9
6. Fractures :	
a. Simple	105
b. Compound ...	66

367

B. Diseases.

1. Bone	25
2. Joints	51
3. Bursæ and tendons	11
4. Talipes	4
5. Ulcers	55
6. Abscesses	17
7. Tumours	9
8. Cancer	26
9. Hernia	11
10. Spinal disease	9
11. Arteries	3
12. Veins	1
13. Eye	27
14. Rectum	10
15. Urinary organs ...	38
16. Unclassified	19

Total of injuries and diseases 683.

316

C. Amputations.

CONTUSIONS.

	Under ten.	Under twenty.	Under forty.	Under sixty.	Over sixty.	Totals.
Head	0	2	1	0	1	4
Face & neck	0	0	0	1	1	2
Chest & back	1	1	5	3	0	10
Abdomen	1	4	4	1	0	10
Pelvis	0	1	0	0	0	1
Hip	1	1	3	1	0	6
Thigh	0	3	4	2	1	10
Thigh & leg	1	3	3	3	1	11
Shoulder	1	2	2	0	0	5
Brain	0	1	0	0	0	1
	5	18	22	11	4	60

SPRAINS.

	Under ten.	Under twenty.	Under forty.	Under sixty.	Over sixty.	Totals.
Knee	0	2	2	0	1	5
Ankle	2	5	4	2	1	14
	2	7	6	2	2	19

Of the total number of contusions and sprains, 71 were in males and 8 only in females. This is in some measure accounted for by the comparatively small number of women employed in arduous work. One case of contusion of the abdomen died. The patient was a man, aged twenty-eight, who had been squeezed between the buffers of two railway waggons. He was admitted at 11 A.M., almost immediately after the accident; no injury could be made out, there was not much shock, and his pulse was fairly full. At 6 P.M. normal urine was drawn off by catheter, and he complained of a feeling of distension in the abdomen; pulse 100. At 3 A.M. next day he became restless, and died in an hour. At the necropsy, twenty-four hours after death, the abdomen was distended. There was no external mark of injury beyond a slight abrasion midway between the trochanter and anterior superior spine on the right side. On cutting through the walls of the abdomen, slight extravasation of blood and other signs of contusion, limited to the hypogastric region, were noted. The abdominal cavity contained some pints of yellow fluid feculent matter. The intestines generally were much injected, and there was a limited effusion of lymph on several coils of the small bowel. A portion of the ileum, opposite its mesenteric attachment, had a transverse wound that admitted a finger easily. On removing the intestines, a large quantity of blood was found behind the peritoneum, which extended on each side up to and around each kidney and below into the pelvis. On making a careful dissection, there was found a laceration of the aorta, just at its division into the common iliacs and slightly posterior, which laceration would admit the top of an ordinary-sized pencil-case. There was no injury to the vertebrae.

Cases of contusion of the abdomen frequently turn out to be more serious than at first sight appeared; for this reason I always direct that such cases, however apparently trivial, shall be admitted, and kept quietly in bed till all chances of danger have disappeared.

One case of contusion of the thigh was followed by the effusion of a large quantity of blood. Such cases almost invariably do well if not interfered with; and in this instance, after the urgent symptoms had passed away, aided by pressure by means of strapping and bandages, nearly the whole of this blood was absorbed in about six weeks.

I have but little to say on the treatment of this class of cases. The main indications have usually been well fulfilled by rest in bed, the application of equable warmth by hot fomentations or cotton-wool, and, when the urgent symptoms have passed away, by gentle passive movement of parts where joints are implicated. My favourite treatment for contusions and sprains about the extremities is simply to wrap the parts well in cotton-wool for some days, with the patient at rest in bed; and I claim for this treatment, as compared with all others I have tried, a more complete absence of all uncomfortable symptoms.

Three of the shoulder cases were not recent, and were fair illustrations of the injury done by keeping parts too long at rest after contusion or sprain. In each case the joint was stiff and the deltoid wasted; but passive motion, aided by faradisation of the muscle, soon improved matters. Why such treatment had not been adopted previous to admission I am unable to say.

WOUNDS, BURNS, AND SCALDS.

Burns.....	4	...	3	...	2	...	11
Scalds	6	...	1	...	1	...	9
	10	4	3	3	0	20	

Of the total 108 cases in these two classes, 95 were males and 13 females. It will be noted that the wounds were most numerous at the ages when men are actively employed, and that the burns and scalds were mostly in young children. Instead of following the usual custom of classifying wounds as incised, contused, &c., I have grouped them chiefly according to their position. Almost all the wounds were lacerated and contused, and of so severe a character as to necessitate their admission. Many were treated in the first instance by *carbolic oil* (1 to 10) dressing, after being carefully cleansed, and, where necessary, parts brought into apposition by silver wire or carbolised catgut sutures. The carbolic-oil dressing is soon replaced by boracic ointment, or, where there is a healthy granulating wound, by the old hospital *lotio rubra*. In every case where it has appeared likely to answer, I have used *styptic colloid* as a primary and permanent dressing. It has been for many years a favourite and successful mode of treatment with me in wounds of all kinds. Some time ago Professor Gamgee, in an admirable paper, drew the attention of the profession to the advantages of the "dry dressing" of wounds,¹ and for years before that the treatment there advocated had been almost a routine treatment with me in the class of cases under consideration. Some surgeons advocate and practise the use of *poultices* as a dressing for wounds. I may say, in dealing with such cases, if there is one thing more than another that I have a horror of, it is a poultice. I fail to see what good it can do which cannot be done much better by other means, and, as a promoter of suppurative and a carrier of all sorts of possible abominations, it has no equal. Whilst saying this I am quite ready to admit that now and again we see cases where a poultice seems to meet the indications better than other applications, but I very seldom see such cases. *Irrigation* with warm carbolised water I have found to answer extremely well in suitable cases, such as sloughy wounds in the extremities, &c., and I have seen sloughy wounds of small extent progress most favourably under a daily dressing of boracic ointment, and the least possible disturbance. I think the value of rest, or rather an absence of continual meddling, is not sufficiently recognised in our ordinary every-day treatment of wounds.

Some few cases of severe laceration of the extremities were dressed *antiseptically*, with favourable results; and *skin-grafting* has in suitable cases aided very much the progress of cicatrisation and the subsequent firmness of the cicatrix. *Splints* have been found valuable in some instances to secure that rest which is so necessary to repair.

CASE.—H. W—, aged twenty-four. On Oct. 2nd, 1879, got his foot squeezed between the buffers of an engine and tender. No bones were broken, but the injury to the soft parts was such that there was considerable doubt about the possibility of saving the foot. It was dressed antiseptically, and again on the 3rd, 4th, and 6th, and boracic ointment was applied on the 10th. By the end of the month he was up, nearly well, and had no symptoms from beginning to end.

In the case of wound of the tongue, the accompanying hæmorrhage was apparently arrested by the application of a solution of perchloride of iron.

The eye cases mostly resulted in blindness from the nature of the accident. In one case, however, where the eyeball had been pierced by the point of a reaping-machine a little above the edge of the cornea, the patient was discharged in sixteen days, without damage to his sight.

Of the two cases of ruptured perineum, one had followed the use of the forceps in a tedious labour in a primipara: the parts had been brought together at once by sutures, but these had given way, and whilst the patient was in the infirmary the whole surface healed soundly by granulation, without any further interference. The other case was in a child, and was caused by a cart-wheel going over the perineum.

Of wounds of arteries, one was of the posterior tibial, near the calf of the leg. It had been under medical care for a week previous to admission, but there had been repeated bleedings. The wounded vessel was cut down upon, and I was fortunate in securing it and tying both ends. The case went on uninterruptedly to recovery.

In one case of stab in the abdomen the wound was deep, and the knife must have gone perilously near the iliac artery. It was dressed antiseptically. On the seventh and eighth days the temperature went up to 102°, being normal each

morning. Five grains of quinine were ordered every four hours. Next day the temperature was normal, and remained so; but on inquiry it was ascertained that, by some mistake, no quinine had been given. This is an illustration of how very careful we ought to be in arriving at certain conclusions in dealing with the action of medicines. It is a difficult subject, and continually confronting one in every-day practice. A medicine is given with a certain definite object, and that object is attained, but the instances (apart from the fact of no medicine having been given, and that fact not ascertained) where it might be wrong to draw the conclusion that the effect was due to the medicine, must be sufficiently numerous in every thoughtful medical man's practice to be very perplexing to him in his endeavour to draw correct conclusions.

The cut-throat cases were all self-inflicted, and were all the result of drinking, except in one instance, where a man suffering from melancholia, having previously murdered his wife, afterwards cut his own throat. All these cases recovered.

Of burns, all those in children were caused by clothes catching fire. I give brief notes of the other three.

Geo. H—, aged twenty-four, was working at the bottom of a boat, when a boy above, whose duty it was to bring down red-hot rivets to him, threw one down instead; and it went inside his trousers and down his leg, producing several burns on its way. These were dressed with an ointment of carbolic acid, oxide of zinc, and resin cerate, as suggested by Mr. Lund; and he was discharged in ten days.

Samuel J—, aged forty-three, got drunk, and slept out all night with his leg in contact with some burning ashes.

Two of the children died, one on the third, the other on the fifth day.

Of scalds, one case was in a child aged three—a scald of the throat caused by drinking water from the spout of a kettle. Edema of the glottis supervened, and there was increasing difficulty of the breathing, for which symptom he was admitted. He was treated by calomel, half a grain every half hour, for two hours; and then one grain every hour all night. (I cannot remember where I saw this treatment suggested.) Next morning his breathing was almost normal, and he was well in four days. All the cases, except two in adults, were caused by boiling water; the exceptions were from hot caustic solutions used at an adjoining paper-mill.

(To be continued.)

NOTES ON CHIAN TURPENTINE, AND ITS USE IN CANCER.

BY PROFESSOR JOHN CLAY,
OBSTETRIC SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

IN the correspondence which has been recently published in the medical journals the efficiency of Chian turpentine in the treatment of cancer has been altogether denied by certain writers. Some have suggested that unsuccessful results may be attributed to the impurity of the drug employed; others have ungenerously questioned the validity of the statements made in my paper, which appeared in THE LANCET for March 27th, 1880. It consequently seems advisable to offer some further general observations, by way of explanation and elucidation, on the subject.

It is a matter for regret that the supply of the genuine Chian turpentine has been so limited, as this has led to the substitution of factitious drugs, the use of which, as I have previously explained, unfavourably influences the results, besides entailing the further disadvantage of preventing a thorough testing of this method of treating cancer. I believe it is a fact that Chian turpentine, in mass, can scarcely be procured in this country at the present time, and therefore it is obvious that the treatment of the disease must be somewhat in abeyance until a supply of the pure drug arrives from abroad. I hope that the difficulty will soon be overcome, as I have been making special efforts to obtain the pure turpentine direct from Scio, and have had three excellent samples of the genuine drug sent to me through the post from that island; a supply may therefore be expected

¹ THE LANCET, vol. II., 1876, p. 886.

shortly, when the purity of the drug at least will be definitely determined. The specimens referred to differ in some particulars from the Chian turpentine which I have previously described, and which had been in stock some years. There are also samples of larch turpentine in the market, which slightly resemble the recently gathered genuine drug. It may be of advantage therefore to the profession to describe each, and to note their differences.

Specimen No. 1 is of a pale, amber colour, and almost entirely free from impurities. It has the fragrant odour peculiar to Chian turpentine well-marked, which is readily perceptible after rubbing a small portion between the thumb and finger. It has a mild terebinthinate taste, which rapidly disappears. On placing a small portion of the drug on a piece of glass, and exposing it to the atmosphere, it considerably thickens after a few days' exposure.

Specimen No. 2. This, obtained last year, is the drug as collected. It contains a large quantity of foreign matter, such as pieces of bark, sand, &c., all of which give it a darker colour than the last-mentioned specimen. Two ounces of this crude product yielded, after straining, upwards of half an ounce of impurities. The strained portion contained still a quantity of minute particles of foreign substances. The taste and odour are the same as in the Specimen No. 1.

Specimen No. 3 resembles soft glazier's putty, but is somewhat whiter, and is of the same consistence. It is Chian turpentine that has been well washed in water, to free it from impurities. It has a mild taste of turpentine, and the peculiar odour is well-marked. If a portion is subjected to pressure between two pieces of glass, water can be readily forced out of the mass.

Three specimens have been submitted to me as genuine Chian which were purely larch turpentine. They may, as alleged, have been gathered in Cyprus. They have a strong odour of pine wood, and are of a browner appearance than the recent specimens just described. On tasting a portion, it appears tasteless for the first minute, after which a strong, bitter, nauseous flavour became manifest, eventually leaving a strong, sickening sensation at the back of the throat, which is slow to disappear. A portion placed on glass, and exposed to the atmosphere for four weeks, showed no signs of thickening, and readily adhered to the fingers.

The degree of solubility of the two kinds of turpentine, in ether and alcohol, is not materially different from that described in a former paper. The mild terebinthinate taste of the pure drug, its peculiar odour, with its power to solidify on exposure to the atmosphere, are characters sufficient to distinguish it from any other turpentine resin.

The results of the treatment of various forms of cancer, in the hands of certain medical practitioners, are alleged to be so different from those obtained by myself, that these gentlemen have thought fit to question the validity of my experiments. Certain results obtained by the use of a remedy, almost forgotten by the therapist, were placed by me unreservedly before the profession; and for the benefit of suffering humanity at least a fair trial of the remedy ought to be given before condemning it. In testing the efficacy of the drug, it is doubtless all-important that the true one should be used. It would appear to be not an easy matter to decide the question of purity, for upwards of three hundred specimens have been sent to me for examination by English and foreign medical men, most of them being guaranteed by the druggists supplying them, and it was a surprise to me to find so few examples of the genuine article amongst them. It will be as necessary now as before to use extreme vigilance in this respect in expectation of the new supply. In a large percentage of cases the factitious turpentine only has been used in the treatment of cancer. In one institution this was particularly so; and after the genuine drug had been tried for about three weeks the results of the two were combined, and a letter forthwith appeared in *The Times*, alleging that the remedy was useless. A similar instance occurred in an institution in this town, where the impure drug was first used, and then after a trial with the pure drug for about three weeks, letters appeared in a medical journal declaring that the remedy was of no benefit in the treatment of cancer. It is plain that sufficient time has not been allowed to elapse for the full effects of the remedy to be manifested, as in these instances of condemnation it has almost invariably been declared inoperative after a few weeks' trial only. Besides the unsatisfactory results which have accrued from the use of the impure drug, the full effects of the pure turpentine have not been gained in some

instances from the drug not having been entirely digested. This has arisen occasionally from its incomplete preparation for administration. In compounding the mixture, freshly-prepared mucilage of tragacanth, B. P., has not been used, and then it rapidly decomposes; or sufficient of the mucilage has not been employed, which causes the resin to separate, and the doses of the medicine, therefore, have been irregular and insufficient. It has been shown in the *Pharmaceutical Journal* that acacia powder might be advantageously substituted for the tragacanth. It is necessary, therefore, to provide that a sufficient quantity of either gum shall be used in the preparation of the Chio turpentine mixture. Where the digestive powers are impaired, an addition of twenty minims of the compound tincture of cinchona to each dose has occasionally proved beneficial. The discontinuance of the sulphur has been advised, in order to make the mixture more elegant and miscible. I believe, however, that the mixture is more efficient, when it is well tolerated, if prepared with the sulphur.

In reference to the pills, if they are not properly prepared they are not always digested. If this is discovered on examining the evacuations, the use of the mixture in conjunction with the pills is indicated; that is, a dose of the mixture should be taken by the patient night and morning, and two pills in the middle of the day, in each case after food. It is advisable, when commencing the treatment, to give only half doses of the turpentine for the first week. Magnesia should not be used as an excipient in the preparation of the pills, but whether this exception ought to apply to the recently collected drug future experiment will have to decide. Pills prepared with magnesia are almost insoluble, and the same remark applies to some coated ones. The pills may be prepared sometimes with ether, to soften the turpentine, or it may be made soft by immersing the mortar in a hot-water bath, the sulphur being added to the mass in its softened state. The latter mode appears preferable, if only to facilitate the digestion of the pills, as if any difficulty is met with in this way they may be roughly powdered and taken in milk or some bland liquid, and then they are generally digested.

The statements made in my original paper as to the efficacy of Chian turpentine in cancer appear to me to be fully confirmed by the additional experience gained in the use of the remedy. In the cases previously reported the cancer has disappeared, and there are no signs of its return. This fact must be considered at least as a complete refutation of the statements, recently and boldly made, that Chian turpentine in the treatment of cancer is useless. The cases just referred to are unique of their kind, for, so far as I know, they are the only instances on record of cancer being cured solely by the administration of an internal remedy. I feel justified, therefore, in stating that uterine cancer at least may be removed by the use of Chian turpentine.

It is a fact which might be expected that most of the cases of cancer which have presented themselves are in an advanced stage of the disease; and more especially is this the case in cancers of the uterus. Yet the treatment continues to be very efficient. My experience does not stand alone in this respect, for several gentlemen have given independent testimony of the good effects produced by the turpentine treatment in cancer of various organs. In my original experiments the turpentine alone was used in order to thoroughly test its efficacy, but it now appears that the use of certain local and general measures undoubtedly promotes the convalescence of the patient. It is possible, therefore, to formulate a line of treatment which shall be successful in cancers of the uterus. Hence, given a case of cancer limited to that organ, and a steady use of the remedy for six or eight months, continued with certain general and local remedies if necessary, and a disappearance of the cancer may be reasonably expected. Eleven cases of uterine cancer under this treatment at the Queen's Hospital, besides a number of others in private practice, so far justify the preceding statements. Some very interesting facts have been observed during their treatment, which I hope to detail on a future occasion.

It is advisable not to be too precipitate in rejecting a case of uterine cancer on the ground of its being too far advanced for treatment. The following case, amongst others, is to the point. Mary B— took her discharge from the Middlesex Hospital, London, about four months ago, and, according to report, was informed that her case was incurable, and that she had not long to live. She had heard of the turpentine treatment, and was very anxious to be under my care at the

Queen's Hospital, but I advised her not to undertake the journey, as I believed the case, from what I heard of it, was too far advanced for treatment. This advice, however, she disregarded, and became an in-patient at the Queen's Hospital. Here she was placed under the Chian turpentine treatment, and improved so much in nine weeks that she is about to return to London with every prospect of soon being cured.

In cancer of the uterus the conclusion expressed in a former paper, that the remedy destroys the cancer cells and causes the death of the growth, is strengthened by experience, and, as a consequence, there is cessation of pain and hæmorrhage in the first instance. But the turpentine at first does not destroy the bloodvessels of the part. As the dead tissue escapes, these become denuded, and give rise to hæmorrhage, especially at the menstrual period. In patients who have past the climacteric period this has not been observed. Ergot has been found of no benefit in arresting the hæmorrhage. Insufflation with three grains each of sulphate of zinc and powdered charcoal, once or twice a day, after syringing the vagina, has proved effectual, and appears to promote the obliteration and atrophy of the vessels. The same end may be attained by using a weak solution of perchloride of iron and glycerine. I have ordered some patients to syringe the vagina daily with equal parts of common vinegar and water, with good effect. When the anterior walls of the vagina are involved; either primarily or from extension, the case is not so suitable for treatment with the turpentine. A vesico-vaginal fistula is soon generally formed, but if this do not happen, cystitis supervenes, and the patient succumbs to the uræmic symptoms which are rapidly developed. Moreover, the turpentine is not well tolerated, but when a fistula forms, it is better borne, and uræmia does not arise.

Excision of the cervix uteri is not advisable, as the disease readily extends to the anterior wall of the vagina subsequently; and then the bladder complications, above described, arise with increased force. The use of the curette is not so objectionable if it is employed to remove only the sloughing mass after some weeks' use of the Chian turpentine, but it has not been deemed necessary to use the instrument, it being all important to preserve as much normal tissue as possible.

The mode in which Chian turpentine effects the removal of cancer was well illustrated in a case of epithelioma of the vulva. The patient, aged sixty, had been operated upon for cancer of the clitoris or vulva. The case was reported in THE LANCET at the time. The patient thoroughly recovered from the operation. About a year afterwards cancer reappeared in the lower part of the vulva and vagina. The growth was again excised, and she made a good recovery this time. About eight months afterwards a cancer appeared on the right labium, and when it was there seen for the first time it was the size of half-a-crown. It was determined to give the Chian turpentine, and the drug was given in full doses three times daily. At the end of the first week there was no alteration, excepting that the cancer was thought to be somewhat paler on its surface, and the surrounding swelling less. Second week: The growth was coated with a secretion of a greyish colour, which appeared to be firmly adherent. Fourth week: The growth was only half its former size. Its surface was somewhat convex; and was considerably thicker than previously, and was surrounded by a ring of a bright crimson colour. One of the resident surgeons of the hospital who saw it remarked that it looked like a small mushroom springing from the vulva. Sixth week: The growth was now diminished to the size of a fourpenny piece, and was still surrounded by the bright coloured ring, but was free from the secretion. The surface did not bleed on being touched. Eighth week: The coloured ring had disappeared. The growth was much smaller, and it had the appearance of a large "seedy" wart, such as is sometimes seen on the hands. Tenth week: The growth remained about the same. Twelfth week: The growth had all but disappeared, and the patient went into the country for a short time, but promised to report herself when she returned.

In private practice three cases of cancer of the rectum are under treatment; two of which are much improved; and one has not been seen again, but a favourable report is given after seven weeks' trial. Three cases of cancer of the stomach are under treatment; one has discharged herself, but the other two have remarkably improved, as regards freedom from pain and capacity of retaining nourishment, though continual sickness existed previously. So far as the

treatment has extended, these cases seem to prove that the turpentine is equally, if not more, efficient in cancer of the stomach than of any other organ. In one case the glands of the neck were much enlarged; but these swellings entirely disappeared after the use of the remedy. Four cases of cancer of the tongue have been under observation. In one case the growth was as large as a cherry, and in four weeks it was reduced to a level with the mucous membrane, and it appears now to be cicatrising.

Several cases of cancer of the face have been very much benefited. In two cases of endothelial cancer of the abdomen and one of cancer of the liver, no benefit seemed to be derived, excepting that in one case there was some alleviation of pain, and an improvement of general health for a time.

In all forms of cancer, where the turpentine has been taken for six or eight weeks, I have found the administration of a tonic to be of advantage, as it promotes the convalescence of the patient, and if the disease affects the uterus or rectum it seems to facilitate the escape of the debris from the destroyed mass, and to promote cicatrization. Four minims of the tincture of perchloride of iron, and three minims of liquor strychniæ, taken three times daily, are recommended; and if there be any pain, which often happens after six months' use of the remedy, six drops of tincture of belladonna are added. A generous diet is allowed. Morphia is not advised. The bowels should be kept daily moved, when necessary, by a mild aperient. After the turpentine has been regularly taken for three or four months, I now recommend it to be discontinued for three or four days in the fortnight. It is probable that future experience will show that, after it has been taken for the above-named period, it will be no longer necessary in the majority of cases, but as a precautionary measure it has been generally continued in the manner just described.

There are sixteen cases of cancer of the breast under treatment in the hospital, and a large number are under observation privately. The effects of the remedy in the first few weeks are, the relief of pain, and a diminution in the size of the breast, which is generally more movable, even when apparently fixed to the walls of the chest; this probably arises from a diminution of the surrounding cancerous infiltration. Time has not been sufficient, however, to speak with definiteness as to the ultimate results. The clinical facts brought out in this class of cases are very interesting and instructive. There is a great probability that the disease is arrested, as after four months' trial of the remedy the morbid growth has not increased in size. As far as can be stated at present, for therapeutical purposes the cases appear to be divisible into three classes:—1. The ordinary scirrhus of the breast, with or without surrounding infiltration. 2. Epithelial cancer. 3. Cases of ulceration after previous operation.

In the first class of cases great interest attaches to the experiment, as indicating how the solid mass is removed. It appears at present to deport itself as if it were a foreign body, and seems disposed to make its way rapidly to the surface; but in the cases where this has occurred the growth is not of an active character, for as the mass comes to the surface a crust forms upon it. This disappears in time, and another forms, while the whole bulk of the mass gradually diminishes in size. It may prove eventually that this is one mode of the removal of the disease. In these cases the growth does not increase in size, but, on the contrary, gradually diminishes.

In the second class—i.e., epithelial cancers—the surface of the growth becomes paler at first, then smoother, as if it had been levelled by friction; sometimes some of the nodules slough away. Then a process of cicatrization takes place. There are two cases in which the new tissue around the growth is quite half an inch in breadth. Two others, about one and a half and two inches respectively in diameter, have entirely healed over.

In the third class of cases the results are so far favourable that the ulceration has not increased in size, but they have not progressed so favourably as the other cases. In several instances the glands of the axilla have been enlarged, but the enlargement has generally disappeared under a steady use of the turpentine.

The importance of these imperfect notes to the profession, and the influence they may have in aiding the treatment of cancer will, I hope, be a sufficient apology for reverting to the subject. At least I trust I have shown that the remedy is not useless. I may, in conclusion, state that in the treatment of these diseases patience and perseverance for a few

months are absolutely necessary. In some diseases which affect the human race, a continued treatment for twelve or eighteen months is often thought requisite. It has, I believe, been here shown that the remedy does produce some influence on the progress of cancer; and it is but reasonable to require that a similar indulgence be extended to the treatment of cancer by this method, as in the chronic diseases just referred to. As the remedy can be taken with impunity for a long period, and if time be granted for the trial of it, I feel that I am justified in stating that its steady use promises excellent future results.

ON INFANTILE RICKETS.

By H. CRIPPS LAWRENCE, L.R.C.P. LOND.

RICKETS, the offspring of mal-nutrition in the fullest sense of the term, is so inseparably connected with many interesting physiological and pathological phenomena that it has attracted the attention of numerous observers, who in recording their experiences have obtained for the disease a literature of its own.

Essentially a disease of infancy, rickets may overstep the borderland on either side; for while Boerhaave¹ wrote, "Never congenital, rickets rarely occurs before the ninth month, scarcely ever after the second year," Dr. Gee, in commenting upon the aphorism, wrote,² "Never congenital! This is, I believe, not far from the truth; but the question of congenital rickets has never been fully investigated." On the other hand, Sir William Jenner³ "saw, some years since, a girl aged nine years who was then only beginning to suffer."

Much has been written respecting rickets in general, and the phases of the affection in particular; but the outcome is not so satisfactory as it might be in reference to the requirements of daily professional practice.

I have placed the term "infantile rickets" at the head of this communication to impress the fact that rickets develops earlier in life than is generally recognised. Taking 2018 cases, including all diseases, observed at the North-West London Dispensary for Sick Children, I found 129 attributable to rickets. Of these the largest proportion first came under my observation between the first and third year. Similar results are recorded by Drs. Brueniche, Gee, Guérin, and Ritchie. In Von Rittershain's statistics⁴ rickets occurred more frequently between the sixth month and second year. A distinction has to be drawn, however, between the frequency of the occurrence of rickets according to the ages at which the cases actually commenced, as compared with the ages at which such cases first come under observation. While ordinary statistics seem to show that rickets as a disease is more frequent between the first and third years, it must be remembered that cases of rickets appearing well developed when first seen represent several cases which have probably been developing for several weeks or months previously. Again, several cases of slight development of rickets are never examined at all, and the mal-nutrition upon which the rickets is dependent receiving its appropriate treatment, such cases pass by unrecorded. Among the 129 cases I observed, it appeared that 68 first came under notice between the first and third year; 39 were noticed between birth and the first year. I believe if my inquiry had been especially directed to the investigation of rickets at the time when the patients first came under observation, 129 would not represent numerically the total number of rachitic cases present in the 2018, which included all diseases. Any number of cases which, upon careful inquiry, might have had to be subtracted from the total of 2018, and added to the 129 cases of rickets, would have to yield a quota likely to increase largely the proportion of cases occurring in the earlier months of infancy. Some such hypothesis will serve to explain apparent discrepancies between the statistics recorded by different observers. Another reason serving to explain the

frequency with which slight developments of rickets are overlooked is to be found in the fact that in practice we are apt to be on the look-out, not for the early manifestations of the disease, but for some fuller development, which mentally accords with the stereotyped descriptions of rickets. Upon this point Guérin, in his "*Mémoire sur les Caractères Généraux du Rachitisme*,"⁵ gives this practical advice:—"It is necessary to avoid the notion that rachitism only commences with the osseous deformity. This manifestation of the disorder belongs to the second stage. Before it affects the osseous system rachitism expresses itself by more or less evident general phenomena, which are only absent in cases where the disease is but imperfectly developed."

I. With the primary stage, to which Guérin refers, are associated by English authors the three following symptoms—viz., (a) sweating about the head; (b) a tendency to lie uncovered when asleep; (c) general tenderness. It is the omission to note these indications of the first stage of rickets that leads to the overlooking, certainly for a time, it may be till too late, many cases of rickets. In general practice the attention of the practitioner is often drawn off from these essential primary phenomena by the occurrence of some intercurrent, accidental complication. Thus it comes to pass that a slight gastro-intestinal disorder, a bronchial or broncho-pneumonic attack, an imperfect attack of laryngismus, or a partial convulsion having occurred, the treatment is directed to the complication, whatever it may be, while frequently no evidence of rickets is sought for. Recovery takes place, and hence, the essential characteristics of rickets being either unnoticed, or, if noticed, soon forgotten, the disease meanwhile progresses, it may be slowly, but surely, to a fuller development. If the attention in practice were, as a general rule, more fully directed to all cases of mal-nutrition,—as an obvious result, cases of undeveloped rickets would be more often detected, and the further advance of the disease not only arrested, but a decrease in the actual amount of rickets also ensured. Another source of misconception arises from the erroneous idea that mal-nutrition is the heritage of poverty, instead of recognising and bearing in mind the fact that mal-nutrition means imperfect nutrition. Mal-nutrition exists largely, owing to their whims and fancies, among the upper and middle classes. From this cause a large number of cases of rickets develops unrecognised among the rich, and not only unrecognised, but unrecorded. As a consequence of imperfectly realising the presence of the prodromata of rickets, and overlooking the likelihood of mal-nutrition in the upper and middle classes, the proportion in which rickets affects infants under one year of age is manifestly underrated.

II. In the second stage of rickets various essential characteristics become evident, to three of which let me refer. (1) Among the osseous deformities, that of "beading" of the ribs; (2) among the rachitic neuroses, that of laryngismus; and (3) that of general tenderness, as a link between the first and second stages of the disease.

(1) The researches of Sir William Jenner⁶ led him to propound the law that "rickets being a general disease, the bones are affected as one organ, just as the arterial system is in the degeneration of age; the consequence of this is, that no one bone is ever affected without all suffering, and that whether the disease manifest itself chiefly by enlargement of the ends of the bones, or by softening of the bones, or by both in a proportionate degree." Again, in reference to the lymphatic system, he adds: "The lymphatic glands are, in regard of albuminoid infiltration, to be regarded as one organ, just as I told you the bones in rickets are to be regarded as one organ. And as in the osseous system we never find one bone only affected with softening, and the other lesions characteristic of rickets, so in the lymphatic system we never find one gland only, or one set of glands only, the seat of albuminoid infiltration. The knowledge of the oneness, so to say, of the glandular system in reference to albuminoid disease, is of much practical importance, inasmuch as we can readily ascertain the state of the lymphatic glands in the groin, axillæ, and neck, while it is difficult to determine by the eye or touch during life the condition of the mesenteric and other internal glands." As the infiltration of the superficial glands thus affords a sure and certain index of a like implication existing in the deeper-seated glands, we have therein also a practical illus-

tration of how rickets as a constitutional disease exerts its influence in reference to location and place.

Now, in the manner in which rickets attacks the osseous system we have, I believe, a valuable practical indication in point of time. I here refer to "beading of the ribs." In the paper already referred to by Dr. Gee⁷ on Rickets, it is stated: "Unquestionable 'beading' of the ribs may occasionally be found in infants of only three or four weeks old. Moreover, I believe that no characteristic alteration in the bones (an essential element in the diagnosis of rickets) can be discovered more early than 'beading' of the ribs." My own, comparatively limited, clinical experience has led me independently to a like conclusion. There are two reasons why "beading" of the ribs is frequently overlooked. To one I referred in a paper on Rickets recently read before the Harveian Society of London in these terms:—"One reason why this essential characteristic is overlooked is that the ribs are out of sight, and as it involves trouble to investigate their condition, not of necessity, but owing to the ribs being out of sight, it often happens that 'beading' of the ribs is not looked for until either notice has been taken of the sweating about the head, restlessness, laryngismus, or enlargement of the wrists and ankles, and then 'beading' of the ribs, being sought for and found, is regarded as a crucial test, confirmatory rather of the other symptoms than as premonitory of their occurrence. Secondly, the frequency with which rickety children present a fat, plump appearance disguises the presence of the enlarged ends of the ribs. If this order were more universally reversed in the diagnosis of rickets, and the child stripped at the first visit for examination, I believe 'beading' of the ribs would be found more often than not to precede the other essential characteristics." Possibly exceptions may arise in which the value of "beading" of the ribs as the earliest symptom of osseous implication in rickets may become questionable; for instance, if ossification were advancing earlier or more rapidly in other directions. I have already mentioned Dr. Gee's observations respecting "beading" of the ribs; if we supplement those remarks by reference to the law propounded by Sir William Jenner relative to the osseous lesions in rickets, "beading" of the ribs at once becomes an early symptom of great practical value in point of time—the analogue as regards the osseous system to that which implication of the superficial glands has been shown to occupy in reference to the other lymphatic glands in rickets in regard to time. In addition to this, "beading" of the ribs is a precursor of primary importance in reference to the osseous lesions in rickets, indicating not only that the second stage of the disorder is impending, but that it has already commenced; and that the treatment appropriate to rickets should be at once instituted to prevent its further development.

(2) The neuroses in rickets are often as misleading in practice as are the early manifestations of the osseous lesions. The explanation of this may be readily accounted for. It arises partly from the age at which rickets attacks the system being an early one. At this age, as we all know, the nervous system is undergoing a rapid development, which reacts upon the economy in a twofold direction. Slight causes suffice to produce phenomena which find their expression through the nervous system, and this whether due to a central or peripheral irritation. Hence the error to which this leads in practice, is a misconception of the significance of one or more symptoms, as indicative of some independent disorder, instead of regarding the symptom or symptoms as being "the consequence of the constitutional disease."

In reference to the convulsions of infancy, it may be stated, on the one hand, in the case of an exanthem, or a thoracic or abdominal inflammation, if an infant or child be attacked thus, the premonitory symptom would probably be a convulsion of less or greater intensity; while in the adult one would expect to be forewarned rather by a rigor. On the other, as Trousseau has shown, convulsions may be induced by some external irritant, such as a pin in the garments of the child transfixing the liver or anterior fontanelle, which being removed the convulsions ceased. Now in rickets the various neuroses acquire a relative value and importance, owing to the method and manner in which they occur in the infant or child.

Of late years much attention has been directed to the etiology of neuroses, and confining our attention to those

concerned with rickets it may be said that laryngismus is one of the most frequent and prominent of the rachitic neuroses.

Sir William Jenner, in enumerating the causes of death in rickets, places the neuroses in the following order: laryngismus; chronic hydrocephalus; convulsions; mentioning especially the frequency of laryngismus in its connexion with the disease. It may be said also of laryngismus, that it is one of the earliest neuroses affecting infancy, and, it may be added, especially the rachitic infant. Upon this point, in a paper "On Convulsions in Children,"⁸ Dr. Gee writes: "Now spontaneous laryngismus is always associated with rickets. For this great middle proposition we are indebted to Elsässer. Forty-eight out of the fifty cases of laryngismus spoken of above were undoubtedly rickety." Of the fifty cases it is also noted that nineteen had eclamptic fits.

Mal-nutrition being so intimate an etiological factor in the production of rickets goes far to explain the frequency with which laryngismus is associated with the disorder. As a concomitant of mal-nutrition, digestive incapacity plays an important rôle in its production. The relationship existing between the larynx and the pneumogastric nerve, by means of its recurrent laryngeal branch, indicates how readily an irritation communicated through the intestinal tract would be transferred to the larynx, exciting its muscles to spasmodic contraction.

To Jacobi and Elsässer is attributed the theory that cranio-tabes (which Elsässer maintains precedes in point of time "beading" of the ribs) itself, arising from undue pressure upon the cranial bones by the brain-substance from within, and from without when the head rests upon the pillow, is intimately associated through the self-same pressure with the production of laryngismus. But Vogel, while admitting the connexion between cranio-tabes and laryngeal spasm as an "irrefutable" fact, requires "further physiological and anatomo-pathological investigations for the conclusive proof as to cause and effect." Be this as it may, many cases of rachitic laryngismus remain to be otherwise explained. Laryngismus thus acquires a position of primary importance among the rachitic neuroses, whether we refer to its frequency or its early prominence. These characteristics increase its value as a symptom in reference to the early diagnosis of rickets.

(3) General tenderness is a third symptom of value in reference to the early diagnosis of infantile rickets. Whether this tenderness be periosteal in nature, as Trousseau maintained; or the result of emaciation and cachexia, as Ritter believed; or "distinctly muscular," as Sir W. Jenner and Dr. Gee have taught,—each and all of these authors associate general tenderness with rickets as a proximate cause. Vogel claims that "the first symptom of rachitis of the ribs, is a marked pain on touching or pressure of the thoracic walls," the production of which can be obviated if the infant be "tenderly raised with one hand under the pelvis, and the other supporting the neck." This observation materially enhances its value as a symptom with reference to the early diagnosis of the affection.

The proposition of Elsässer, that cranio-tabes is the earliest evidence of osseous implication in rickets, may be regarded as still *sub judice*. If we believe, however, with Dr. Gee that "beading" of the ribs is the first and most reliable, demonstrable evidence of an osseous lesion in rickets, and with Vogel that general tenderness is "the first symptom of rachitis of the ribs," then this general tenderness at once acquires the position of being an important link between the symptoms of the first and second stages of rickets.

In conclusion I would remark: 1. That rickets as a disease is frequently developed earlier in life than is generally recognised. 2. That the symptoms of the first stage, though frequently recognised, such as sweating about the head and a tendency to lie uncovered, are soon forgotten, and the rickets, the occurrence of which they predicate, meanwhile develops. 3. That between this primary stage and the second stage of well-marked osseous deformity there are intervening symptoms, to which in practice sufficient value is frequently not attached. 4. That in general tenderness we have a symptom of great value, indicating the onset of the second stage of rickets, being its earliest manifestation. 5. That in "beading" of the ribs we have a more marked, demonstrable evidence that the second stage of rickets has commenced. 6. That in laryngismus as a neurosis we have

⁷ Vol. iv. of the St. Bartholomew's Hospital Reports.

⁸ St. Bartholomew's Hospital Reports, vol. iii., p. 103.

probably one of the earliest evidences that rickets has invaded the nervous system.

If the above symptoms be overlooked or ignored, our next acquaintance with the disease will probably be in a fully developed, it may be an irremediable, form.

Oxford-terrace, Hyde-park.

EXTRACTION OF A REVOLVER BULLET FROM THE SKULL.

BY SAMPSON GAMGEE, F.R.C.S.,

SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

A FEW minutes before 1 A.M. on Wednesday, the 22nd ult., I received an urgent note from my house-surgeon, Mr. Westwood Moore, reporting that a gentleman had just been admitted into the Queen's Hospital after firing a revolver bullet into his right ear. I proceeded to the institution at once, and found the patient in bed. He was sensible, with a fair pulse. A little blood was oozing from the right meatus, and the ear was most sensitive to touch, but not wounded; only slightly bruised at one point. On the left side of the neck, reaching below the larynx, and upwards on to the cheek, was a large, hot, brawny swelling, which, the patient informed me, had been in process of formation for about ten days. Everything had been done most judiciously and promptly for the patient's comfort by the hospital staff. Restoratives, ice, &c., were continued; and I resolved not to interfere, beyond removing a strong metal plate with artificial teeth from the upper jaw.

The patient continued for the next two days in much the same state, as denoted by the subjoined extracts from the temperature chart. For brevity, I only quote the maximum numbers:—23rd, temperature 99.4°, pulse 96, respiration 16; 24th, temperature 99.4°, pulse 104, respiration 22; 25th, temperature 99.3°, pulse 96, respiration 24.

The swelling on the left side of the neck increased greatly, and on the 25th, I could feel indistinct fluctuation in its centre. Through an incision I gave exit to about one ounce and a half of very fetid pus.

Next morning (Sunday, 26th ult.) the swelling just referred to had so much diminished, and the patient was generally in such a favourable condition, that I determined on exploring the right ear; while Mr. Brett, our resident obstetric surgeon, administered ether. There had been a slight but continuous oozing of bloody serosity from the earhole.

With a narrow scalpel I made an incision in the roof and floor of the meatus, so as to admit the tip of my little finger, a metallic probe having previously detected a rough, hard substance within the passage. The inner ear was evidently blocked; but whether by bone or bullet, or both, I could not tell until I introduced a Nélaton porcelain probe. This soon solved the problem. On withdrawing it I found a shiny black mark on the white bulb; only lead could produce that. The diagnosis cleared, arose the question what to do, for the obstructing body seemed immovably rammed into the temporal bone.

I allowed the patient to wake, to have a little nourishment, while messengers were sent to all the members of our honorary staff urgently requesting them to favour me with their opinion in consultation. Their response was most cordial, their counsel and practical assistance most valuable. My friend, Mr. W. G. Archer, of the general hospital staff, was also good enough to attend and assist me, as was Mr. T. P. Salt, our surgical mechanician.

The propriety of attempting the extraction of the bullet having been unanimously agreed upon, rose the question of means. Mr. Brett again placed the patient in a beautiful sleep under ether. Bullet forceps proved of no use. I made all the room I prudently could with the knife, but there was no space for ordinary bullet extractors. By working with the left hand a steel elevator, as a lever against my right index-finger as a fulcrum, I succeeded in extracting the bullet. It weighs 126 grains, and one of the bullets left in the revolver weighs precisely the same. The patient quickly regained perfect consciousness, and took liquid nourishment. Next morning the temperature had risen

to nearly 103°; pulse 144; respiration 24. The state in the evening was: temperature 101°; pulse 136; respiration 24. Perfect rest enjoined; ice internally and to the head, and attention to the bowels by enemata. Some refreshing sleeps were enjoyed. There was no sickness and no paralysis for the first thirty-six hours after the operation; but then coma rapidly supervened; the pupils became fixed; the body motionless. At 10.30, 28th ult., temperature 103.6°; pulse 168; respiration 17. Death occurred twenty minutes later, forty-two hours after the operation.

The post-mortem examination was conducted by Dr. James Oliver, with the assistance of Mr. R. Fitch. There was a considerable amount of sero-purulent effusion in the cavity of the arachnoid, and its vessels were injected. A thin, purulent deposit covered the surface of the brain, especially of the right hemisphere. Much punctiform redness interspersed the cerebral substance. On removing the dura mater a ragged fissure was visible through the roof of the right temporal bone. On laying open the interior of the petrous portion it proved to be tunnelled with an irregular dirty cavity with broken walls, demonstrably the place of lodgment of the bullet.

In the next issue of this journal I hope to offer some comments on the case, with illustrations of the bullet as moulded into the inner ear, and also of the lead mark on the porcelain probe.

(To be concluded.)

TREATMENT OF CHOLERAIC DIARRHŒA BY THE HYPODERMIC INJECTION OF MORPHIA.

BY W. HARDMAN, M.B. EDIN., C.M.

IN THE LANCET for Sept. 27th, 1879, appeared a communication from me on the subject of the treatment of choleraic diarrhœa by the hypodermic injection of morphia. I will recapitulate the conclusions I there ventured to draw from an extensive experience of over three years' routine use of this method:—

1. Choleraic diarrhœa can be always immediately stopped by the administration of morphia hypodermically.

2. If severe diarrhœa have persisted over two hours in spite of the administration of morphia or opium by the mouth frequently, the hypodermic injection of morphia should be at once resorted to.

3. If cramps and collapse be present, the purging persisting, no time should be lost in administering morphia subcutaneously in full dose.

4. The treatment is absolutely free from danger, even if temporary suppression of urine or albuminuria be present.

5. Where not curative the treatment is diagnostic, enabling us to foretell with certainty the advent of dysenteric symptoms.

6. The best preparation of morphia for this and other hypodermic purposes is the sulphate, on account of its smaller liability to undergo change into apomorphia. For a knowledge of this last fact I am indebted to my friend, Mr. H. O. Thomas of Liverpool. Obstinate vomiting may persist for twelve to forty-eight hours after the purging is stopped, but need occasion no anxiety. It is the purging that kills.

I am anxious for the beneficial and gratifying results of this treatment to be as widely known as possible; and with this object in view I give a few illustrative cases.

CASE 1.—Mrs. S—, aged fifty-six, has been purged violently all day. Watery stools; now nearly unconscious and voiceless. Purging continues. A third of a grain of sulphate of morphia was administered hypodermically at once. This was on July 23rd. She was never purged again, and was convalescent on the 25th.

CASE 2.—On August 6th was called to a delicate woman, a Mrs. T—, aged about fifty. She had purged all night violently; and up to my seeing her, which would be about 9 A.M., I found her passing colourless, watery stools, sometimes involuntarily, and vomiting almost constantly. She was pale, sunk, cold, with blue lips and finger-nails, fear-

ully cramped, hoarse weak voice, and quick, small, irregular pulse. The people of the house thought her dying. Administered one-third of a grain of sulphate of morphia hypodermically, at once.—Aug. 7th: Never purged again.—Aug. 8th: Convalescent.

CASE 3.—Miss M—, choleraic diarrhœa for twenty-four hours. Cramped; motions like rice-water. Gave a third of a grain of sulphate of morphia at once. Next day convalescent. Never purged again after injection.

CASE 4.—July 19th: Mr. F—, choleraic diarrhœa for twenty-four hours. Gave half a grain of sulphate of morphia at once.—July 20th: Not another stool. Convalescent.

CASE 5.—Was called up on July 26th to a Miss H— about 4 A.M. Was sent word she was dying. I found her unconscious on the floor in a faint, having been purged violently involuntarily. The motions were like rice-water. I ascertained that the purging had been going on since 8 P.M., and that between that time and 4 A.M. she had been moved copiously more than twenty times; she had also terrible vomiting. Gave half a grain of sulphate of morphia hypodermically at once.—11 A.M.: Not purged again; rallying.—July 27th: Convalescent, but weak; never purged again since the injection.

CASE 6.—Miss N— was attacked on August 7th with severe choleraic diarrhœa. Gave one-third of a grain of sulphate of morphia at once.—8th: Convalescent. Never purged again.

CASE 7.—Was called up about 6 A.M. on Aug. 11th to a Mrs. D—, aged sixty. They sent word she was dying. Found she had suffered from diarrhœa for some days, which had become choleraic during the last twelve hours, having had from twenty to thirty motions during the night, which were pale, colourless, and odourless; vomiting incessant; cold sweats; pinched features; voiceless; blue lips; cold extremities; and very thready, weak, irregular pulse; fearful cramps all over; semi-conscious; passing stools involuntarily; countenance changed. Gave half a grain of sulphate of morphia at once. 11 A.M.: Never purged again; rallying; vomiting continues.—Aug. 12th: No more purging; vomiting better.—Aug. 13th: Convalescent and up. This was a very bad case.

CASE 8.—Was called on Aug. 12th to a Mr. S—, who had been vomiting and purging all day and night. I saw him in the evening, receiving a message that he could not last long. Found him hoarse, pinched, and cramped. Gave one-third of a grain of sulphate of morphia at once. Aug. 13th: Never purged again. Up.

CASE 9.—Was called about three weeks ago to a Mr. D—, who had been violently purged about twenty-four hours, with violent cutting pains in belly; had also vomited. Gave half a grain of sulphate of morphia at once. Motions loose and watery-yellowish. Saw him again same evening. Purging, after being better some hours, had returned as bad as ever. Gave opinion that case would develop into dysenteric diarrhœa. Next morning motion still watery, but on slanting the vessel, the characteristic bloody slime was seen adhering to the bottom. He was gradually cured by the administration of ipecacuanha and opium.

Whatever the evacuation, cutting pains in the belly usually denote that the diarrhœa is of a dysenteric nature, and will not yield to morphia alone. Cramps occur only in choleraic diarrhœa, the purging of which is usually, but not always, painless in the commencement.

CASE 10.—On August 10th, 1879, was called to a Mrs. W—, who had been seized with violent vomiting and purging in the night. Temperature 104°. Gave a mixture containing chalk and opium after every liquid stool. 8 P.M.: Worse. Motions assuming the rice-water character. Temperature 101°. Motions come from her without her knowledge if she moves. One teaspoonful of the medicine every quarter of an hour until the purging stopped. 10.30 P.M.: Worse than ever. Gave half a grain of sulphate of morphia at once.—Aug. 11th, 10 A.M.: Better. Laughing and cheerful. Says in about a quarter of an hour she felt the injection produce a most wonderful effect. A pleasant, warm feeling spread all over her, and then the purging ceased. Was not purged again, and not the least sleepy.—12th: Convalescent.

CASE 11.—Was called to an old lady, aged sixty-seven, on August 21st, 1879, who had been weakly and failing some time, and who had been purging violently all night. Motions watery, with yellowish flocculi. Gave mixture of opium with chalk after every liquid stool, but after a few hours' trial the

purging was as bad as ever. Gave a quarter of a grain of sulphate of morphia hypodermically.—9 P.M.: Purging, which stopped after the hypodermic injection, has returned again, and she has been purged five times. Mixture of opium with chalk, one drachm every quarter of an hour until purging stopped.—Aug. 22nd: Still purged and vomiting severely. Motions yellowish, watery, with yellowish bilious flakes floating in the fluid. 9 P.M.: Motions assuming the greenish slimy dysenteric character. Patient was now treated for dysentery, and in a few days made a good recovery.

CASE 12 is with difficulty distinguished from genuine Asiatic cholera. Miss F—, a delicate elderly spinster, was seized on Sept. 16th, 1879, about 11 P.M., with violent vomiting. This continued until 12 P.M., when violent purging was superadded; these continued with violence until 1.30 A.M., when I was called up to her. I gave a mixture of opium with chalk after each liquid stool. 2.30 A.M.: Was called up again, as they thought her dying. I found her nearly unconscious, cramped all over body and legs, vomiting violently every minute or two, purging every few minutes, the purging being involuntary and under her. She was showing the whites of the eyes, and the countenance was changed. She was certainly all but gone. Gave at once two-fifths of a grain of sulphate of morphia hypodermically. She did not feel the prick of the needle in the least. 10.30 A.M.: Never purged since injection, but vomiting tiresome. 8 P.M.: Vomiting a little better.—Sept. 18th: Convalescent.

CASE 13.—On August 12th I was called to a Mr. M—. He began purging on the 10th, and got worse and worse until I saw him on the evening of the 12th, when he stated that he had been purged more than thirty times in the preceding twenty-four hours. Motions watery and yellowish. I gave him a mixture containing compound ipecacuanha powder, to be taken every hour until the purging stopped.—13th: Purged all night; very weak; voice going. Gave at once half a grain of sulphate of morphia hypodermically.—14th: Never purged again since injection. Convalescent.

These thirteen cases, which are taken, almost at random, from a considerable number of which I possess notes, illustrate my propositions. Cases 1 to 8 are ordinary cases of choleraic diarrhœa, where hypodermic injection of morphia was resorted to at once, and constituted the sole treatment. One dose usually is sufficient, and convalescence is rapid. Cases 9 and 11 illustrate the proposition that if the purging return it will ultimately prove dysenteric. Cases 10, 12, and 13 show the rapid and complete results of the hypodermic administration of morphia after the equally complete failure of opium by the mouth. I can hardly conceive it possible that this plan of treatment will not prove equally successful in Asiatic cholera, for the more purely choleraic the cases the more perfect and rapid the result. There is a form of diarrhœa attended by vomiting of bile and the passage of yellow, powdery, liquid stools. This form of diarrhœa seems due to an excessive formation of bile by the liver, and will not be cured by the administration of morphia hypodermically. As regards genuine choleraic diarrhœa, I can only repeat what I wrote in THE LANCET last year, that "in the whole range of medicine there is no one deed so gratifying to both patient and practitioner as the administration of a hypodermic injection of morphia in choleraic diarrhœa."

Blackpool.

A HARELIP TROCAR AND TUBE.

Contrived by

SURGEON-MAJOR E. AMBROSE FITZGERALD,

BENGAL MEDICAL SERVICE.

THIS little instrument, to which I wish to draw attention, is devised on the trocar and cannula principle. The piercing portion of the trocar is thin and round, with the point strong, sharp, and somewhat spear-shaped, and made of the best steel. The tube, about two inches long, is made of coin silver, sufficiently stout as not to bend on ordinary pressure or straining, and admits of slight expansion and contraction in its entire length, so as to fit on accurately to the trocar. When a harelip operation is to be performed, the edges of the fissure having been pared, the trocar, armed with a silver tube

is thrust through a quarter of an inch from the raw edges of the fissure, close under the mucous lining of the lip. This being done, the trocar is withdrawn and the tube allowed to remain. Two tubes are sufficient for most cases of harelip. The margins of the fissure being brought well in apposition, a piece of strong silk or carbolised thread is twisted round each silver tube separately. Long narrow strips of sticking plaster are then passed over the lip, between the tubes and above and below them. The tubes can as a rule be safely withdrawn on the sixth or seventh day after the operation.

ST. GEORGE'S HOSPITAL.

EPITHELIOMA OF THE RECTUM REMOVED AFTER A NEW PLAN WITHOUT INJURING THE SPHINCTER ANI; RECOVERY.

(Under the care of Mr. ROUSE.)

FOR the following notes we are indebted to Mr. C. T. Dent, late surgical registrar.

I. C—, aged sixty-four, married, was admitted in May last with an epithelioma of the rectum of about six months' growth, situated on the left side of the bowel, about one inch above the anus. The growth was flat, sessile, of about the area of half a crown, and limited to the mucous membrane and the sub-mucous tissue. The deeper parts felt apparently uninvolved.

On June 17th Mr. Rouse removed the growth in the following manner. A curved incision, an inch and a half in length, was made, just outside to the external sphincter, and parallel to the outline of that muscle. The skin was then dissected up outwards for a short distance, so that the outer circular fibres of the sphincter were exposed. The muscle was then drawn over towards the middle line. By introducing the finger into the rectum, the growth was pressed into the external wound, and it was then cut out, together with that part of the wall of the rectum to which it was attached. In the way an opening, about the size of a half-crown, was made through the bowel. After the closure of the skin wound but a small cavity could be felt, corresponding to the former situation of the growth. The hæmorrhage was very slight.

Opium was given in order to keep the bowels confined for some days. The recovery was almost uninterrupted. For some few days slight feculent discharge took place from the wound, but after about three weeks this had completely ceased, and the patient then had entire control over the contents of the rectum. As a matter of fact, scarcely any fæces escaped, but the suppuration resulting during the granulation and closure of the cavity possessed a fecal odour. When the patient left the hospital, about a month after the operation, the power of the sphincter was perfectly normal. The general symptoms were much relieved.

Remarks.—The advantages of this method of operating, in suitable cases, are obvious. In the instance described above, it is true, the growth was of small extent and limited to one side of the bowel. There seems no reason, however, why this operation should not be equally applicable to growths of much larger size. The advantage of preserving the sphincter intact is patent; no doubt, in some cases an operation of this nature might advantageously be substituted for complete removal of the lower end of the rectum. Certainly, numerous cases have been recorded where no incontinence of fæces followed the latter proceeding; but still this method of operation gives the patient additional security against a highly unpleasant condition, without any additional concomitant risk.

DUNDEE ROYAL INFIRMARY.

THREE CASES ILLUSTRATING THE DIFFICULTIES OF RECOGNISING INTERNAL CANCER.

(Under the care of Dr. SINCLAIR.)

THE following cases were all instances of well-marked malignant disease, though the symptoms were by no means characteristic.

CASE 1. *Cancer of lesser curvature of the stomach.*—D. S—, aged fifty-five, weaver, was admitted on Aug. 5th, 1879. The patient had been in good health till six weeks before admission, when he became troubled with "pain and weakness in the stomach." A week later he gave up work on account of oedema of feet and legs, and took to his bed. He had passed only half the usual quantity of urine during the last few weeks.

On admission his face was pale, but not cachectic, and the conjunctivæ were pearly; there was no jaundice; the appetite was much impaired, the tongue clean, and the bowels were regular; pulse 100, weak; heart sounds weak, but clear; sonorous râles in chest; considerable oedema of feet and legs; urine normal. Diarrhœa soon set in; the stools were ochry, but did not contain blood; there was no vomiting; the tongue was red and fissured. On Aug. 21st, the abdomen was distended, tympanitic in front, dull in flanks; dulness changed with change of position; the hepatic as well as the splenic dulness was normal; pain in right hypochondrium (which was referred by patient to "the stomach") continued. On Sept. 22nd there was still absence of vomiting, and had been since admission; the urine was free from albumen and casts, and the patient complained of nothing but weakness and loss of appetite. He, however, became steadily weaker, and died on Oct. 2nd.

Necropsy.—The body was fairly nourished. There was very great oedema of feet, legs, and genitals. There were old adhesions of the pleura on both sides. The bronchial tubes were congested, and there was oedema at the bases of the lungs. Weight of lungs 45 ounces. The pericardium bore traces of old inflammation, and contained a normal quantity of fluid. The heart substance was firm and the valves were competent. The coronary vessels were enormously dilated and very tortuous. Weight of heart 7½ ounces. The peritoneal cavity contained several pints of serum. Both orifices of the stomach were free from disease. The lesser curvature was occupied by a soft cancerous mass, suppurating in some parts, and everywhere breaking down readily under the finger. There was no disease elsewhere in the organ. The pancreas was so adherent to the stomach for four inches of its length that it could not be separated without causing perforations. Weight of stomach 17½ ounces. The liver was fatty; weight 37 ounces. The pancreas was unusually hard, but otherwise normal; weight 4½ ounces. The capsules of the kidney were adherent, and the kidney tissue was pale and hard. Weight of both 9 ounces. The spleen was normal in structure; weight 2½ ounces.

Remarks by Dr. SINCLAIR.—Emaciation, weakness, anorexia, occasional slight gastric pain and hydrops cachecticus were the only symptoms pointing to malignant disease of the stomach, but, in the absence of vomiting and discernible tumour, they could hardly warrant a diagnosis till it became evident that the man was sinking rapidly. The marked oedema of the lower limbs, without an evident cause in the heart, liver, or kidneys might, however, have awakened suspicion earlier.

CASE 2. *Primary cancer of greater and lesser curvatures and of the pyloric orifice of the stomach; secondary cancer of liver.*—G. R—, aged fifty-three, labourer, admitted Dec. 27th, 1879. The patient was in good health till six weeks before admission, when he began to suffer occasional but not severe pain in the umbilical, right hypochondriac, and right lumbar regions. He had no vomiting. The bowels were kept in action by laxatives for some time before admission.

On admission he was in no distress, but he appeared apathetic and was emaciated. There was no notable cachexia or jaundice. There was tenderness on pressure over the hepatic region. The hepatic dulness reached the umbilical level in nipple line, and within an inch of it in the ensiform line. The urine was dark amber, acid, 1030, with heavy deposit of urates and a little albumen.

He had no vomiting while in the hospital. About the beginning of January he became jaundiced, and died on Jan. 5th.

Necropsy.—The peritoneal cavity contained about two pints of bile-stained fluid. The liver was much enlarged, and presented evidence of old peri-hepatitis on the right lobe. The whole of the upper and lower surfaces were studded with cancerous nodules. On section the entire organ was infiltrated with cancer and cancerous juice. The upper surface was adherent to the diaphragm; weight eight pounds ten ounces. The stomach was adherent to the liver, pancreas, and diaphragm. On opening the stomach, about thirty polypoid masses were observed, varying in size from a large pea to that of a horse-bean, and situated mostly in the greater curvature towards the pylorus. The whole lesser curvature was occupied by a hard cancerous mass plainly visible on the peritoneal side. The mass extended into the pyloric orifice, which was somewhat narrowed; weight twenty-one ounces. The spleen was rather friable. The kidneys were pale, but otherwise normal.

Remarks by Dr. SINCLAIR.—Although primary cancer of the liver is a comparatively rare affection (according to Frerich's analysis 22 being primary and 69 secondary in a total of 91 cases), I hardly doubted that this patient suffered from the primary disease. This opinion even now seems quite tenable had there been no post-mortem examination, because there were no gastric symptoms, and there was indubitable evidence of painful enlargement of the liver. The value of this case consists in showing that, however exceptionally, a patient may die of gastric cancer affecting every important part of the organ except the cardia, without showing notable symptoms of the disease even when the morbid growths have increased the stomach to something like five times its normal weight.

CASE 3. Cancer of splenic flexure of colon, causing fatal obstruction.—On the evening of Feb. 4th, 1880, at the request of Dr. Low, K. H.—, aged forty-nine, a rather weak-minded female, was seen, in consultation, at the East Poor-house. The patient was in her usual health till a week before, when she complained of loss of appetite and constipation. There was no vomiting till the 3rd of February, when some bile was ejected. On the following morning there was some stercoraceous vomiting. There had up to this time been no complaint of pain. The abdomen began to swell for the first time on the 3rd, and within twenty-four hours the distension had much increased. Urine was passed freely till the afternoon of the 4th. Except constipation she had no urgent symptoms till the forenoon of the Sunday. She then had some opium. The countenance was pale and anxious; pulse feeble. There was pain only in the right iliac fossa. There was great and general distension of the abdomen, which was tympanitic all over. Some lumps of hardened feces were found in rectum. The uterus was small, and free from adhesions or displacement. An enema of soap and water and liberal doses of opium were ordered; but the woman died suddenly, three hours after the consultation.

Necropsy.—The intestines in the neighbourhood of cæcum were covered with soft feces, which had evidently come from a perforation about the size of a sixpence in the anterior wall of the cæcum. The small and the greater portion of the large intestines were enormously distended with gas and fluid feces. The distension was particularly great at the cæcum, the walls of which were thinned at several parts. The ascending and transverse colon were so much distended that the latter resembled the stomach. At the splenic flexure of the colon an annular malignant stricture was found. Here the dilatation suddenly ceased, and the descending colon and rectum were found to be of much smaller calibre than usual, and contained some lumps of hardened feces.

Remarks.—It was evident that this case was a very grave one, though, from the short duration of the illness, and the absence of all the characteristic symptoms of malignant disease, the theory of cancer was never entertained. Even had the tympanitic distension of the bowels been much less, the neoplasm, on account of its small size, could certainly not have been detected. It is just possible that a more intelligent patient might have furnished information that would have led to a correct opinion.

ALTRINCHAM HOSPITAL.

STONE IN THE BLADDER; LITHOTRITY, WITH EVACUATION; CURE.

(Under the care of Mr. T. TORKINGTON BLEASE.)

G. H. S.—, aged sixty-eight years, a scripture reader, of sallow complexion, first came under treatment in November, 1879. He had been in delicate health for about eight

years, and had consulted many surgeons. He had spent the winter, from Dec. 27th, 1870, to May 9th, 1871, in the Hospital for Consumption at Ventnor. He had frequently suffered from hæmoptysis, and during the same period had often had hæmaturia. At the time he applied to Mr. Blease the urine constantly contained a large quantity of pus, there was frequent desire to micturate, and there was great pain in the pelvic viscera and in the penis.

The patient was in great agony, having recourse to hot baths three times daily, and linseed-meal poultices over the sacrum and abdomen. The bladder had been examined six times by four surgeons during the eight years he had been suffering, but no allusion had been made by any of them to the viscus containing a stone. The patient hesitated a long time before he would submit to another sounding, but on Jan. 10th, he allowed an instrument to be passed into the bladder, and a stone was at once discovered. The nature of the case was explained to the man, and, with the sanction of his colleagues, Mr. Blease advised the operation of lithotomy, with rapid evacuation, on Bigelow's method.

On Jan. 29th he was placed under chloroform, and the lithotrite was used. Thirty grains (dry weight) of a calculus was washed out, when it was found inconvenient, in consequence of the smallness of the bladder, to use the lithotrite longer. After this and the subsequent operations the circulation and temperature remained undisturbed.

On Feb. 9th the lithotrite was used again, and 117 grains of stone were washed out. On Feb. 18th the lithotrite was used a third time, and fifty-three grains were removed in a similar manner. There was still a very small portion in the bladder, but it could not be seized, and on March 3rd it was thought desirable to send the patient out of hospital for a short time. From domestic causes he was unable to return before June 14th, when a fourth operation was performed, and every particle, thirty grains, was removed.

Remarks.—No doubt few operations would have been necessary had not the bladder been so much diminished in size. After each operation the troublesome symptoms were less, and the patient might have left the hospital the day after the last crushing, but he remained six days, when he was discharged cured. The man had doubtless been suffering many years from stone in the bladder, but although he had been examined by four different surgeons, and the symptoms had grown more severe each year, no operative interference had been suggested. The case affords additional proof how tolerant a bladder may become, even when in a very unhealthy condition. The stone was composed of uric acid, with an oxalate of lime nucleus.

Reviews and Notices of Books.

Hygiene and Treatment of Catarrh. By THOS. F. RUMBOLD, M.D. St. Louis: Geo. O. Rumbold & Co. 1880.

THIS is a semi-popular and readable little work upon the prophylaxis and treatment of a "common cold"—a subject to which the writer tells us he has long given much attention. It abounds in advice, for the most part sensible enough, although here and there it would not be difficult to differ from the writer, who seems to have been carried away by his subject. For example, the closing chapter is devoted to an exhaustive counterblast against tobacco, the use of which he maintains is positively pernicious to a catarrhal patient and of very questionable benefit to the healthy; since, he maintains, its effect is invariably that of a depressant, whilst locally it produces a permanent state of congestion of the mucous membrane of the upper respiratory tract. There is no denying the truth of some of his statements, but it is not possible to follow him through his whole indictment. The book is well-planned. It opens with chapters on personal hygiene, in the matter of head-coverings, the treatment of the hair, clothing, &c., and many valuable hints are given on these points. The writer is especially severe and somewhat satirical upon the prevailing fashion of female dress and head-attire—to the use of which he attributes rightly enough many catarrhal attacks. He is a firm believer in the efficacy of inunction, not only for the head and

feet, but for the body generally; and his favourite unguent for this purpose is vaseline. He speaks strongly about the importance of free ventilation of the sleeping apartment, and urges, rather extravagantly, that disturbed mental states predispose to catarrh, and warns people against giving way to anger and ill-temper. On this latter point some may object that he has mistaken the *post hoc* for the *propter hoc*, for it is notorious that a common cold does not generally conduce to an equable frame of mind. Upon remedial measures he is especially urgent in inculcating the use of frequent and thorough cleansing of the nasal and laryngeal passages, and shows that the Weber douche does not fulfil its requirements, for as commonly applied it leaves untouched portions of the nasal cavities, where secretion most frequently is lodged. Moreover, he has had cases where inflammation of the antrum and otitis have been set up by its employment. He has therefore discarded this apparatus in favour of a spray douche, which he figures and describes. A chapter is also devoted to the cleansing of the ears, for which he employs a modification of Luce's injector. The widespread prevalence of catarrh, the scanty consideration usually given to it both by laymen and medical men, render this book one of some utility, and in spite of a tendency to magnify the importance of the subject it will repay perusal.

Alcohol Tables, founded on the Tables of Fownes and Drinkwater. By OTTO HEHNER, F.C.S. London: Churchill. 1880.—This useful compilation gives the percentage of alcohol by weight and by volume, and the percentage of proof spirit for every unit of specific gravity, from 1.000 to 0.7938—that is, from pure water to pure alcohol. It will save analysts much trouble.

Tables for the Analysis of a Simple Salt: for use in School Laboratories. By A. VINTER, M.A., late Scholar of Gonville and Caius College, Cambridge. London: Longmans & Co. 1880.—We are already flooded with little books of this kind. Why they are published is a mystery, each one seems so like the one before it.

ABSTRACTS OF

INTRODUCTORY ADDRESSES.

ST. MARY'S HOSPITAL.

INTRODUCTORY ADDRESS BY WALTER PYE, F.R.C.S.,
ASSISTANT-SURGEON AND LECTURER IN PHYSIOLOGY.

AFTER welcoming in a few words the old friends of the school who had met together to celebrate the beginning of another medical year, and those who were as yet strangers to their school and to their work, the lecturer warned the latter against entering the profession unless they were prepared to follow it for its own sake, and urged those whose motives for joining it were interested or unworthy to give up the task now before it was well begun. In discussing the prospects of those who honestly loved their work, he said that while the getting of large incomes was the fortune of very few, still none could fail, except through their own fault, to earn money enough for comfortable subsistence. The prospects and standing of the profession, however, were not to be judged by a mere money standard; in the eyes of the outside public its importance was being every year more recognised, and the social position of its members was steadily rising; this was not due to a better appreciation by the world outside of the higher aims of medicine, but to a steady improvement in the culture and education of medical men. The lower standards, however, of previous education, he held, were not yet high enough nor broad enough, and he urged that a scientific education, which should be really preliminary to the professional education at the hospital schools, should be made compulsory for all; and that the schools themselves should be relieved from the necessity of teaching the elements of sciences which were only allied to

medicine. He pointed out that not only would this course leave the student free to give his whole attention to his proper work as soon as he came up to the hospital, but that the systematic cultivation of scientific habits of thought was of the greatest importance to medical men, even though in after years the actual details of what they learnt did not remain in their memory. Men came up to the hospital, not to learn to be chemists or botanists, but to be doctors; but the latter they could not be, in the highest sense of the term, unless they had gone through a previous scientific training.

The course of study of a medical student seemed to be peculiar in this, that it grew steadily more and more pleasant, even more and more easy, to pursue, as the student advanced in it. No argument was needed to prove that both naked-eye and microscopic anatomy were to be mastered; but he held that the study of physiology was even more essential, and he insisted on the importance of progress in this branch of their work, and on the necessity which lay upon all who hoped to advance their art of studying it both normally and pathologically. He pointed out that medicine at the present day was advancing, not as it had been for the last two hundred years, simply by the accumulation of clinical experience, but by striving as far as possible to reduce its practice to the conditions of that of an exact science—to establish a new empiricism; and he said that though the ideal end of this school of practitioners would never be reached, still, every step towards it was a step in the right direction, and that the only way in which advance could be made was by the earnest study of physiology. The progress in the way of exactness in medicine which had been made during past years was real, and gave promise of an abundant harvest in the future. He strongly urged the junior students to get their first professional examination over as soon as possible, and till that was done not to attempt to do any clinical work in the wards. That examination—or those examinations—over, the most enjoyable part of their student's life lay before them. This was divided into work in the wards as dressers or clinical clerks, and work in the out-patient rooms and casualty room. In the wards of the hospital students were to recollect that the standard of illness was very high, and that those cases which looked commonplace by contrast with still more severe ones there would be regarded as very serious ones indeed under any other conditions. He reminded them that the more common illnesses in the wards would be the ones they would most frequently see on leaving the hospital; and he urged them to take careful and continuous histories of all the patients they had to watch. When surgical dressers also, they were advised to study to acquire habits of manual dexterity and mechanical ingenuity in dealing with the varying difficulties of their cases. He pointed out that in the out-patients' rooms their work and the lessons they had to learn from their patients differed considerably from their experience in the hospital wards. In these latter patients were put in the best possible condition for getting well. In the out-patients' rooms few of the really ill were able to receive the treatment they most required—namely, food and rest in bed; these rooms, however, were the great school for the getting experience of illness and of habits of rapid diagnosis and self-dependence; but they were to bear in mind that the treatment was generally a compromise, and not that which patients ought properly to have. He advised the students to haunt the hospital, and to know its aspect at all hours of the day and of the night; but he reminded them that during their life in London they were not to neglect to cultivate their faculties in other directions; they were to recollect that they had to be in the highest sense men of the world, able to appreciate the cultured thoughts and words of others; and in order to be able thus to get the best out of their lives they should not pass by those storehouses of literature and art that nowhere were so large or so easily entered as in London.

He warned them against the use of books as means of getting that knowledge which should be learnt at the bedside; text-books should be merely used as means for sorting or pigeon-holing knowledge previously acquired; and the really original professional works should not be studied until the student was well-established in the practical knowledge of disease.

In conclusion, he reminded the students that in the case of St. Mary's the school and hospital had one foundation and could only exist together; they had common interests,

common hopes and fears, and while they could look back upon an unsullied past they must not forget that the original scheme of the hospital exceeded by far its present size, and that its usefulness, both as a great charity and as a medical school, fell, from its limited accommodation, far short of what was required by the district in which it was placed or designed by its founders. Their hopes for its enlarged prosperity in the future were high, and could not but be soon fulfilled if they determined in the present to sustain its good name and good fame as they had received it, till the time came for them to hand it down stainless to their successors.

WESTMINSTER HOSPITAL.

INTRODUCTORY LECTURE BY DR. DONKIN,
SENIOR ASSISTANT-PHYSICIAN TO THE HOSPITAL.

THE lecturer took for his subject the duty of the doctor towards society and some of his derelictions therefrom, considering also the reciprocal attitude of society to the doctor, and showing that the widespread ignorance that existed of the nature and scope of science made undue demands from the profession, and must be held partly responsible for the dishonest quackery that still disfigures it.

Attention was called first to the wide foundation of varied knowledge on which medicine was based, and one of the first duties of the doctor towards society was shown to be the endeavour to keep abreast of the advancing tide of knowledge. Modern invention and recent research were doing much to increase the difficulty of this work and add to the responsibilities of the profession. At the same time it was none the less incumbent on the practitioner to keep firm hold of the knowledge accumulated during past ages, which, though to some extent wanting in definiteness and communicability, was invaluable to the practical physician, and should be appropriated by the student with as much care as the results of the latest lights of science.

One more important point to remember was the part played by the mind in the causation and modification of many diseases, the doctor's whole duty not being always discharged by an examination of the patient, which was strictly physical in the narrowest sense of the word. To obviate errors from the neglect of this consideration a careful and sympathetic study of human character was necessary.

The difficulty of fulfilling these duties being obviously great, examples of transgressors were not far to seek. The quack still flourishes under various aspects, and prominent among this class were those who professed to have a definite "system" of therapeutics, and were always ready to give a plausible explanation of their method of procedure to those who were entirely ignorant of the subject. A complete system of therapeutics was impossible while the knowledge of disease remained as imperfect as it was; he, therefore, who professed to be the possessor of such a system was an impostor. Quacks of this order ignored the scientific studies of the causes of disease, and looked no further than the symptoms, thereby flattering the intellect of the patient, whose vision was similarly limited. The practice of the homœopath, both concealed and confessed, was an instance of this, in that it made capital out of the ignorance of the public and the common desire of men to know by what method they were cured. Men, after all, had no scientific right to expect that any given disease should be curable, and a more scientific knowledge of what disease is in its relation to health would show them that it was more rational to be surprised and thankful that any of their ailments should be cured than to grumble at the powerlessness of medical art to dissipate them all. There was not, nor was there reason that there should be, any real parallel relation between drugs and disease, although it had always been the popular superstition that there existed in nature a remedy for nearly every ill, if only the doctors could find it out. Of this superstition the quacks of all ages had taken, and were taking, advantage. They had their reward, for they flourished well.

A prominent form of quackery in orthodox ranks was that of exaggerated specialism, which was based on the plausible and popular teaching that the body could be studied piecemeal. Hence arose a posse of doctors for almost every organ of the body; hence also a perverted use of instruments in themselves valuable—instruments rendering possible an in-

spection of parts of the body invisible to the unaided eye and beyond the patient's own power of observation. Might not this very possibility evoke sometimes from its lurking-place that evil spirit of designing Quackery which sank the profession in the trade of medicine, and tempt it to turn invention to its own base ends by forcing the "regular" practitioner, whose body it too often inhabited, to raise a false alarm of a disease which he declared himself specially able to cure? And a fancy not over-fertile might picture a perhaps fabulous or professedly curable ailment of one organ of the body exclusively treated by such perverted art, while fatal maladies were running their silent course unrecognised or, still worse, unreported by the skilled observer. It was to be deplored that ever the ark of science should be touched by such unholy hands.

The ignorance of the public as to what the science and art of medicine really were, and a widespread hostility to scientific method, coupled often with an arrogant assumption of knowledge, were important factors in the production of these men, who disgraced their profession. Were the "dry light" of science to shine more widely, the various emotional "systems" and opinions of the time would fade away, and we should hear less of the motley view of anti-vaccinational, anti-vivisectional, homœopathic, vegetarian, and total abstaining fanatics. It was on pabulum such as these that the quack of modern time lived and flourished—on the credulity of the classes who think they know. A more general teaching of the elements of biological science would tend largely to benefit the community, and by enlightening, the public would help both to purge and strengthen the ranks of the medical profession.

RECENT RESEARCHES ON THE ACTION OF DRUGS.

THE problem of the antagonism of poisons, which seems destined, for a long time, to be a *questio vexata*, has been re-examined by Mr. J. N. Langley, at Cambridge, in reference to certain statements of Rossbach. The latter affirms that when a tissue has been paralysed by any one alkaloid it can neither be stimulated nor restored to its normal condition by any other alkaloid. In the submaxillary gland, for instance, if the chorda tympani nerve has been paralysed by atropin, no amount of physostygmmin or pilocarpin can, according to him, make it again irritable. He holds that in glands there are two parts to be considered, the nervous and the glandular part, that small doses of alkaloids affect only the nervous part, while large doses affect the glandular part in addition. After atropin has paralysed the chorda tympani, pilocarpin may still affect the gland cells, but they cannot be affected by it if the dose of atropin was sufficiently large to affect the gland cells also. Langley has ascertained certain facts which militate strongly against this view. If a small quantity of atropin be injected, the secretion, which is arrested, can be restored by pilocarpin. If a stronger dose of atropin is injected, the same dose of pilocarpin will no longer restore the secretion. Hence, according to Rossbach, this large dose of atropin has affected the gland cells as well as the nerve. But Langley finds that a still larger dose of pilocarpin will again restore the secretion. Thus, whether the larger dose of atropin acts on the cells or not, the pilocarpin must have been antagonistic to it.

Certain recent researches into the effect of large doses of strychnia have brought to light some most remarkable facts. In poisoning by this agent the convulsions and toxic action are remarkably lessened by artificial respiration. This was first shown by Rosenthal, who asserted that double the ordinarily-fatal dose was necessary, under these circumstances, to cause death. Experiments which, in the main, confirm these statements have been made by Leube, Pauschinger, and Buchheim. M. Richet, however, has recently informed the Académie des Sciences of the startling fact that when artificial respiration is maintained, a dose of strychnine 100 times that which is usually fatal may be administered without causing immediate death, and that the effects are altogether different from those which result from ordinary

doses. The quantity of strychnia which is fatal to a dog of ordinary size is two or three milligrammes. If one centigramme is injected beneath the skin, or into the saphenous vein, of a dog, in the trachea of which a cannula has been placed, the animal is seized in about a quarter of a minute with a violent convulsive attack, which would be fatal were it not for artificial respiration. Under the latter, however, the attack ceases in a few seconds, and the heart, after a period of irregular action, resumes its normal pulsations. Still larger doses of strychnine can be thus injected without causing the death of the animal. The toxic phenomena vary according to the dose injected. There is first a tetanic period, and later a convulsive stage characterised by violent, incessant, spasmodic contractions of nearly all the muscles. A little later, when the quantity of strychnine injected exceeds one centigramme per kilogramme of body weight (say one decigramme, a grain and a half, for an average-sized dog), a stage occurs which may be termed choreic, marked by violent rhythmical shocks, recurring at intervals of three or four seconds, and separated by periods of almost complete resolution. When the dose exceeds four centigrammes per kilogramme of body weight (say half a gramme, or seven grains, to a medium-sized dog), the choreic shocks do not occur; there is a final stage of complete resolution, when reflex action is abolished, spontaneous respiratory movements have ceased, and the heart contracts with frequency but regularly. The pupil, dilated at the onset, becomes strongly contracted. Arterial blood pressure, raised at the commencement of the poisoning, gradually falls, and the rectal temperature varies correspondingly, rising during the convulsions to 105° or 106° F., to fall to 96° during the period of resolution. Dogs and rabbits, to which these large doses have been given, may be kept alive four or more hours by artificial respiration. If the latter is interrupted for a few seconds, say for half a minute, the heart stops, and the animal is dead. Loss of blood, even of a small quantity, will also cause death. In order to ensure success in these experiments, the strychnine has to be injected with a certain slowness, an hour being given for the injection of half a gramme (seven grains). The artificial respiration must be vigorous, and success is more readily obtained with rabbits and small dogs than with larger dogs. If instead of these large doses, very small quantities are employed, say one milligramme per kilogramme of body weight, death occurs rapidly by syncope. The cardiac failure is not at first fatal, but after three or four attacks the animal dies. When the dose injected is fifty times as much these syncopal attacks do not occur, and it can then be ascertained that the pneumogastric has scarcely any action upon the heart. The muscles preserve their normal irritability. The action of the motor nerves is lessened, but is not abolished. Thus the complete absence of spontaneous movements is to be ascribed to the effect of the strychnia upon the spinal cord, rather than to the loss of the functions of the motor nerves, or of their terminations. The animal is in a condition analogous to that produced by chloral or alcohol. We cannot, from these experiments, derive much hope of dealing more successfully with strychnine-poisoning. As the poison is eliminated, and its dose thus lessened, its effect upon the heart increases, and death results from syncope. But in cases in which it is important to prolong life for a few hours, this might be effected by prompt tracheotomy and vigorous artificial respiration.

Bromide of ethyl has been found by M. Rabuteau to be an efficient internal remedy, chiefly as a substitute for chloroform, over which, however, it does not appear to possess special advantages. Given by the stomach, it was found to relieve gastric pain, without affecting the appetite. Inhalations readily relieve convulsive cough, and, introduced on cotton-wool into the external meatus, it relieves the pain of otalgia without causing any irritation. Claude Bernard showed that the vapour of chloroform and of ordinary ether hinder the germination of seeds, and M. Rabuteau has found that it is equally true of bromide of ethyl and of bromide of amyl. He finds also that all the ethers have the same effect. The experiments were made with cress seed. But the property of germination is merely restrained. Seeds kept for thirty-seven days exposed to the vapour of bromide of ethyl or bromide of amyl, germinated, when placed under proper conditions, in two days. The question then presents itself, Have these substances a similar action upon plants which are in full progress of growth? Growing cress was exposed for two hours to an atmosphere saturated with vapour of bro-

mide of ethyl; it then appeared feeble, the leaves hanging down, and it continued in this condition for a day or two, and then revived, but exhibited considerable retardation in its growth compared with other plants of the same age. The leaves of heliotrope become brown, and die in the course of two hours. Acetate of ethyl is somewhat less powerful. Cress lives after it has been exposed to the vapour for three hours, but does not survive an exposure of six hours. Heliotropes are only killed by an exposure of three or four hours. The action of acetate of ethyl is also correspondingly less active in animals.

The effect of salicylic acid on muscular contractility has been studied by M. Livon. Frogs poisoned by this substance present tetanic phenomena. Tracings obtained from the contracting muscles show that the salicylic acid causes an increase of excitability, followed by a considerable diminution and by an irregularity in the latent period. The tetanus which occurs may present two forms. One resembles closely that which results from electrical stimulation, and a second, altogether different, which presents a rhythmical character. In the latter the muscle is in the condition which has been termed "contracture," which continues until the muscle is exhausted, and will no longer respond to faradisation of the sciatic nerve. This exhaustion is apparently not due to any effect of the drug upon the muscles; its action seems to be solely upon the nerve centres. The phenomena of the rhythmical tetanus lead M. Livon to believe that the rhythmical action of the heart is not due to any peculiarity in its muscular structure, but solely to its different mode of stimulation.

The inutility and even harmfulness of salicylate of soda in typhoid fever was well established, both in this country and in Germany, soon after the introduction of the drug. Objections to its use in this disease will not be lessened by a recommendation of it recently made by M. Hallopeau, since he had three deaths in twenty cases. M. Labbé has tried it in erysipelas and found it useless.

Sulphocyanide of potassium has been regarded as a "muscular poison," but this opinion is opposed by some experiments of Dr. J. V. Laborde, the results of which have been described in a series of articles in the *Gazette Médicale de Paris*. He first ascertained that a relative tolerance could be established when the dose does not exceed a gramme; and then, by almost daily administration, he kept an animal under its influence for more than six months. The general health was but little disturbed until the end of the fourth month, when considerable emaciation occurred, and little food was taken. The condition of muscular contractility examined in the thigh or leg at different periods, never presented the least alteration appreciable by any ordinary means of investigation. The cardiac pulsations lessened notably in force and number in accordance with the depression of the nutritive functions. The animal appeared, however, to be in no danger of death, when it suddenly succumbed to a comparatively trivial operation, the intravenous injection of water. From this and many other experiments M. Laborde concludes that the muscular contractility is not primarily or directly affected by the sulphocyanide of potassium.

Euonymin is a drug which, although of some previous repute in America, was introduced to the profession in England mainly by Dr. Rutherford's investigation into its power as a cholagogue. It has been little employed in medicine, but a case in which pseudo-membranous colitis was treated by it successfully has been published by M. Blondeau. The case had resisted many courses of treatment, but disappeared in six days on five centigrammes of euonymin night and morning.

GUY'S HOSPITAL.—On the 28th ult., at the ordinary meeting of St. George-the-Martyr, Southwark, Mr. Robins moved, "That a petition be presented to the honourable House of Commons by the vestry, praying an inquiry, if possible, by a committee or commission appointed for the purpose, into the management of Guy's Hospital, in the parish of St. Thomas, Southwark, an institution founded in the last century by Thomas Guy for the relief of poor sick people, endowed with an income which has now become perhaps nearly £50,000 per annum, for this purpose; and which institution there is great reason to believe is, and has been for some time past, most inefficiently and improperly managed." The motion was seconded by Mr. A. Hawkins, member of the London School Board, and, after a lively discussion, was carried.

THE LANCET.

LONDON: SATURDAY, OCTOBER 2, 1880.

It is much to be regretted that a strong and widespread feeling of dissatisfaction exists at present in the Indian Medical Department, and that its development has been in a considerable degree due to official mismanagement on the part of the authorities in India. When it was decided to be necessary that the dual administrative staff of the medical services should be abolished, instead of promulgating in its entirety a well-considered scheme of reorganisation, the authorities in India published a General Order by which the Indian Medical Service was deprived of a number of administrative appointments, without a hint being given of any intention to compensate it for the loss, except in the case of the actual holders of the posts to be abolished. It cannot be a matter of surprise that this General Order created dismay in the department and called forth energetic remonstrances against the injustice which it appeared was to be inflicted by it. After a lapse of ten weeks the authorities published a second General Order creating a number of administrative appointments, chiefly in connexion with the civil department, which, if judiciously made, might be fairly considered as compensation for those which had been withdrawn. It is difficult to understand upon what principle this second General Order was so long kept back if the new organisation were settled, and if it were not it is still more difficult to conceive how the Indian Government could break up so important a branch of the public service without having made any arrangement for its future management. It is, at best, an example of intense official stupidity. Though the discontent created by the first General Order was, to a considerable extent, removed by the second, it was again brought into action by the manner in which the newly-created appointments were filled up; two of the Surgeon-Generalships were given to Surgeons-Major, and the third to an officer who was made Deputy Surgeon-General only a few days before, and apparently with a view to his promotion. In defence of this course it has been stated that the officers thus promoted were men of long service and of marked ability. But two of them had previously declined promotion to enable them to retain lucrative appointments, and, although there was no regulation on the subject, the custom of the Service has been that such refusal was a bar to all future promotion. At one time in the British Army officers were occasionally, for a similar reason, allowed to decline promotion by brevet, sometimes oftener than once, and when it suited their convenience, or their post was required for some other favoured individual, they were promoted *per saltum* to the place on the list of Generals which they would have occupied had they never refused it. This, however, was found to give rise to so much favouritism and jobbery that it was stopped, and we believe no case of the kind has occurred for the last thirty years. It is to be regretted that such a course was permitted on the present occasion, when even under the most favourable circumstances many cases of hardship must

have unavoidably occurred in connexion with the new organisation. The agitation which arose out of the circumstances above detailed naturally led to a consideration by the officers of the general position of their service, and brought out grievances which, under more tranquil conditions, might have passed unnoticed for many years. These have been discussed in the documents issued by the Indian Medical Officers' Defence Committee, and in our columns and those of our contemporaries, and we now propose to take a brief general view of them and of the remedies proposed for them.

The first grievance to which we shall advert is the difference of relative rank granted to Surgeons and Surgeons-Major in the British and Indian Medical Services respectively. In the former the Surgeon ranks on first appointment as Captain, and the Surgeon-Major of twenty years' service as Lieutenant-Colonel, according to the date of commission; while in the Indian Service they rank respectively as Lieutenant and Lieutenant-Colonel but *junior* of the rank. This is a disparity between officers of the same grades and employed on the same duties which ought at once to be abolished. A step of honorary rank is granted on retirement after twenty years in the British, but only after twenty-five in the Indian Medical Service. This is really a point of very little importance, but it appears to create an invidious distinction between the two classes which might be advantageously removed. In the Indian Service the Surgeon must undergo an examination before he is eligible for promotion; as this ordeal has been discontinued in the Army Medical Department it seems only fair that it should now be given up in the Indian, especially as it frequently involves considerable inconvenience from the necessity of the officer proceeding to the head-quarters of the district for the purpose. The time spent at home on sick leave is not allowed to count as service for retirement. It may probably be necessary to guard strictly against any abuse of sick leave, and to put some limit to the length of time which it might be permitted to cover, but we think the subject deserves the consideration of the authorities, with a view to reduce the hardship involved in such a rule in the case of officers who have lost their health from causes not within their control. The scale of retired pay in the Indian Service demands reconsideration. It is much lower than in the British, and wholly inadequate. In former days, when it was supplemented by the Medical Funds, and when the opportunities of making money were greater, while the expenses of living in India were less, it may have been sufficient, but in the changed state of these matters it is certainly a serious though happily a remediable grievance. We have repeatedly called attention to the niggardly hand with which honours and decorations are bestowed on the Indian medical officers, and in this respect also an equitable adjustment is required. That only one officer of that service should be decorated with the Order of the Bath is far from creditable to the military authorities of India, for we presume that it is solely from the want of a recommendation on their part that such a state of things exists.

It appears to us of importance that a definite rule should be laid down with reference to officers declining promotion on the grounds of personal convenience. This should not be permitted at all, or, if ever sanctioned, under very

special circumstances, the refusal ought to be a bar to any future promotion. It also seems very desirable that a regulation should be made to prevent the promotion of a Surgeon-Major to Surgeon-General without having served in the intermediate grade.

Another important change which appears to be called for is the introduction into the Service of the grade of Brigade Surgeon. This would tend to remove the feeling which has been created of injustice to the officers from the reduction of the number of Deputy Surgeons-General. The arguments in favour of the creation of this grade in the Army Medical Department apply with equal force to the Indian Service, and it is difficult to see how such an important difference in the grades of two departments working together can exist without creating a feeling of discontent in the one from which it is withheld.

There is still another point to which we must refer. It has been stated as a grievance by some of the Indian medical officers that all the Surgeon-Generals of the military branch are to be held by officers of the Army Medical Department, and a claim has been advanced that half of these should be given to Indian officers. But it must not be forgotten that the three Surgeons-General of the military branch withdrawn from the Indian Service have been replaced by three in the civil branch. If, then, the demand for the restoration of half of these appointments were complied with, it could only be done at the expense of the Army Medical Department, and we have not yet seen any proposal to compensate that department for the loss to which it would thus be subjected. If the Indian Service is to be rewarded in this manner, it must be prepared to give up some equivalent in exchange—perhaps one-half of these civil appointments. It has been made subject of complaint, also, that the Sanitary Commissioners are not to be reckoned as equal to Deputy Surgeons-General's appointments till the officer has put in twenty-six years' full-pay service. It has always appeared to us that these officers should have been made from the first Deputy Surgeons-General. They belong to the military branch, and are merely lent to the civil; and it would have been much better if they had been created Deputy Surgeons-General for sanitary duties. We trust this solution of the difficulty may yet be resolved upon by the Government.

The great obstacle in the way of these improvements is, of course, the increased expenditure involved in them. Among the chief reasons for the recent changes were the useless expense of the dual administrative staff, and the necessity for retrenchment so far as was consistent with efficiency. The adoption of the measures above recommended would, however, absorb much more than the amount which has been saved by the newly-introduced system. It is a vital question, therefore, how the financial difficulty is to be met. Probably this might to some extent be effected, as it was in the British Service, by the adoption of the station hospital system. It has been found to work well in the one department, and there seems no good reason why it should not do so in the other. On active service, as has been proved in the Afghan war, it carries with it many advantages, especially with reference to the diminished amount of transport required. The inquiry which the Marquis of RIPON is understood to have directed to be made into the grievances

of the Indian medical officers might, with great propriety, be extended to include the whole working of the Department in India. We have no reason to doubt that, with the advantage of the experience acquired from the several re-organisations of the Army Medical Department during the last twenty years, a scheme could be devised for the efficient working of the Service with a staff considerably less than has been deemed requisite under the old system, and that the increased expenditure necessary to remove complaints and to keep the Service as attractive as it has hitherto proved, might be met by the reductions which could thus be made in the Department, not only without loss, but probably with a considerable gain to its working powers.

It can hardly be said that we are even yet in a position to satisfactorily account for the production of the first sound of the heart. The generally received explanation is that it is composed of two elements, a valvular and a muscular—although physiologists differ upon the exact share taken in its production by the contraction of the heart-muscle, and some even doubt its share at all. A paper was read at the meeting of the Paris Academy of Medicine on Aug. 31st, by M. ROSOLINO, of Athens, in which (so far as we know) an entirely novel and not unreasonable explanation was broached. This observer maintains that the sole cause of the first sound is the vibration of the chordæ tendinæ in the systolic eddy of the blood-stream. He argues that if it were due to the flapping together of the valve-cusps, it should be produced mechanically by simple traction on the cusps by the cords; but experiments on the human and equine heart fail to bear this out. A simple membrane which from being lax is suddenly stretched produces a sound; but the valve-cusps exist under more complex conditions—since they are more or less fixed by the chordæ, which are inserted not only on their free margin, but also on their surface. The cusp is not therefore free to move in its whole extent, like an unattached membrane; and it is rendered tense by the general contraction of the papillary muscles. Nor is the first sound due to the passive closure of the valve by the blood-column. VALENTIN thought this might be the case, and endeavoured to prove it by showing that a similar sound was produced by suddenly distending with fluid a coil of collapsed intestine; but he could not have obtained it had he artificially enlarged the calibre of the intestine previously, and then stretched its walls. If the sound is abolished by hooking up the valve, it is because the procedure also destroys the meshwork of the chordæ tendinæ. Again, M. ROSOLINO has produced a similar sound by projecting a current of water over cords attached at both ends, and disposed like the chordæ tendinæ. He rejects the muscular hypothesis, not from his own research, but by the facts advanced by CHAUVÉAU and FAIVRE. Nor is the theory of its production by the friction of the blood against the walls of the auriculo-ventricular orifice tenable, since in that case the bruit produced in aortic constriction, where this friction would be most developed, should partake of the characters of the first sound instead of a blowing character. The ventricular wall, tense and solid as it is, cannot vibrate like the chordæ, which from their tenacity, their tension, and their freedom from attachment except at the extremities, are in a condition to allow of true vibrations. As stated above,

we are not aware that this explanation has been before offered. It is ingenious and worthy of consideration, but at the same time it must be obvious that in cases of simple regurgitation from dilatation of the cavity, the condition of the chordæ may be almost unaltered, and yet the first sound will be abolished, or rather replaced, by a murmur; and it is difficult to entirely throw over the view that the actual impact of the cusps, and their sudden tension during systole, is not a great element, if not the sole cause of the sound.

THE questions to be discussed by the Council of the Hospital Sunday Fund on Tuesday next, on the report of the Distribution Committee in reference to objections to the grant to the Eastbourne Convalescent Hospital, are very important; but they readily admit of being misrepresented or misunderstood. They are nevertheless also very simple. The Hospital Sunday Fund is a fund raised by all the churches and chapels in the metropolis. Christians and Jews, Protestants and Roman Catholics, vie with each other one day in the year in contributing towards the support of public hospitals, conducted on public principles, and open to all comers without distinction of creed, and on an understanding that once admitted their creed will be respected. Obviously such a fund possesses two characters which, unhappily, are not often blended. It is at once a religious fund, and yet a perfectly unsectarian one, that should be distributed without suspicion of being applied to indirect or sectarian purposes.

It will be seen that in the very nature of the case it is desirable to exclude from the discussions of the Hospital Sunday Fund all merely theological questions—such as the baptism of patients in hospitals, the propriety of urging them to go to the confessional, of holding up to a dying dissenter an image of the Virgin Mary, &c. &c. These are all questions that are clearly coming thickly and quickly to the front. Even a more fundamental question is threatening—namely, whether hospitals are to be considered as medical or as ecclesiastical institutions. It requires very little observation to perceive that a certain religious party is disposed to look upon a hospital as a special field for doing theological work, and that the theological or ecclesiastical purpose transcends any merely therapeutical purpose as the soul transcends the body. It is very clear that if this doctrine is to be pushed the medical profession will have to make it clearly understood that hospitals are for the cure of sick bodies, and not places for disturbing the mind with the petty questions which divide one church from another. And unless we underrate the common sense of the public, the public will insist upon this view being taken, and will refuse to allow hospitals built or supported by public contributions to be used for personal or sectarian purposes.

But though such questions are indirectly involved in the discussions which are to take place in the Council of the Hospital Sunday Fund, and will be far more directly raised unless the party that is trying to convert hospitals from medical to ecclesiastical uses shows more discretion and moderation than it has yet done, they do not essentially arise at the present moment.

The real question to be determined on Tuesday is far more simple and hopeful. It is this: Has the Eastbourne Con-

valescent Hospital “a committee duly constituted”? If not, has it any claim on the Fund? Or has the Council of the Hospital Sunday Fund any power to grant it an award? Of all the laws of the Hospital Sunday Fund, none is more clear and none is more indispensable than Law 4, which reads thus: “Those hospitals and dispensaries [only] which are managed by a committee duly constituted, and which produce their printed reports, with balance-sheets audited for the last three years, shall be *allowed* to participate in the Fund.”

The institution at Eastbourne, finely situated and in many respects exemplary, has not a committee. Were a scandal or an abuse to arise in it, it would be very difficult to appeal to any visible or tangible authority. It is, in fact, not at present a public hospital. By the admission of the deputation which waited on the Distribution Committee on Tuesday, it is virtually a private hospital, reared by the munificence of two or three ladies, and committed by them to four trustees, of whom one only is active and the others do not appear. Such an institution may have all sorts of virtues, and no doubt it does a great amount of good. But it is not a public institution. It cannot be made so until its subscribers are called together and duly elect a committee and other officers. The public and the profession will perhaps be surprised to hear that no meeting of the subscribers of this hospital has ever been held. When such a meeting shall have taken place, the institution will have a strong claim on the Hospital Sunday Fund, and this Fund may trust to the representation of all interests on the committee to be appointed. Such a committee is promised, and that is a great step gained by the discussion which Dr. GLOVER has raised. But until it is appointed the hospital is not a public institution, and any grant made to it by the Hospital Sunday Fund will be made in violation of one of its most proper and indispensable laws.

Annotations.

“Ne quid nimis.”

WORKHOUSE VITAL STATISTICS.

THE statistics of workhouse infirmaries are valuable from a sanitary, medical, and a social point of view. It is to be regretted that such statistics are not more generally available, and that they are not compiled with a greater regard for uniformity than is now the case. A report has recently been published which deals with the statistics of the Shoreditch Workhouse Infirmary for the year ending Lady-day last, prepared by Dr. Forbes, the medical officer. Although the report is open to one or two objections, the value of its figures stimulates the wish that similar information were forthcoming for other kindred institutions. In the first place, however, we are obliged once more to enter a protest against such reports dealing with years ending on any other day than Dec. 31st. The report before us deals with the last three quarters of 1879 and the first of 1880, a manifestly inconvenient arrangement. During the four quarters 2356 cases were treated in the infirmary, showing a further steady increase upon the annual numbers since November, 1872, when it was opened. The admissions, which were 1281 in the first year of the institution's existence, were 1804 last year. The average daily number of inmates resident in the infirmary during the year under review was 447. It is noticed that, although the admissions

were considerably greater than they had been in the previous year, the average number resident showed a decline. It appears that some time since, when the appointment of a resident assistant medical officer was urged upon the guardians, it was suggested that one of the probable results would be a decline in the number of residents through the cases being cured more rapidly. The medical officer in the present report is able to point out the apparent realisation of this probability. Fears have been at times entertained that the development of the Workhouse Infirmary system would tend to encourage and increase the amount of pauperism, and that the infirmary might become the portal to the workhouse. So long, however, as the admission to the infirmary is subjected to proper supervision and classification, a well-conducted and thoroughly efficient Workhouse Infirmary ought to have an opposite effect upon pauperism. Bearing in mind the large amount of pauperism due to ill-health, any system which secures the most skilful treatment of the poor in sickness must tend to reduce pauperism. In the Shoreditch Infirmary the cases of illness admitted from the Workhouse are treated in a different block from that to which out-door cases are directly admitted. This useful classification prevents habitual paupers from being associated with those who are only temporarily pauperised by sickness. Dr. Forbes urges the great desirability of establishing Convalescent Homes in connexion with the Metropolitan Workhouse Infirmary, which, in affording incalculable benefit to discharged patients, would frequently establish recoveries, which otherwise become relapses. Without attaching too much importance to the crude mortality statistics of such an institution as a Workhouse Infirmary, it is worth noting that the recorded completed cases in the Shoreditch Infirmary during the year were 1896, of which 303, or nearly 16 per cent., were deaths, and 1593, or 84 per cent., recoveries. In the absence of other similar statistics with which to compare the Shoreditch figures, we will not venture to offer an opinion upon the rate of mortality that prevailed. It is evident, however, that when 16 per cent. of the cases admitted prove fatal, the proportion of serious cases constantly under treatment must be large indeed; and we know that the average number of all cases under treatment during the year was 447. It would be useful to know what is the medical and nursing strength of an institution with so heavy a charge. With regard to the 303 deaths in this institution, we are told that 21 were of infants under three years of age; 7 were of children aged from three to twenty; 135 of adults aged between twenty and sixty; and 140 were of persons aged upwards of sixty years. No less than 189 of the deaths were attributed to diseases of the respiratory organs. It is satisfactory to learn that although 67 deliveries occurred during the year in the lying-in wards, no death followed parturition, and no case of puerperal fever occurred in the wards. Some interesting statistics are given of the cost of maintenance of patients, from which it appears that it averaged about 5s. 3d. per week, made up of 4s. 7d. for food, stimulants, and necessaries, 4½d. for clothing, and 3½d. for drugs. The total cost of maintenance is remarkably low, and affords evidence of strict economy combined with good management. With respect to the cost of drugs not averaging more than 3½d. per week, we can only express surprise, having regard to the serious nature of so large a proportion of the cases. We trust, however, that neither the guardians nor the medical officer would sanction a dangerous system of paltry economy in drugs. We are glad to see a dietary table, but the efficiency of the diet depends so much upon what is ordered and dispensed as "extras," that it would be useless to discuss it seriously. It is noted that the paid-nursing system continues to work satisfactorily. During the severely cold and foggy weather of last winter it was found necessary to burn gas constantly in order to keep

up the temperature of the wards. Dr. Forbes reports that the rate of mortality was not excessive during that period, and attributes this fact to warmth of temperature maintained in the wards, and to the free use of stimulants. The cost of stimulants (beer, wine, and spirits), nevertheless, during the year was not more than 5d. per head per week. Dr. Forbes' figures are full of interest, and we hope that other Workhouse Infirmarys will follow the example set by the Shoreditch Infirmary.

HOSPITAL REGISTRATION.

WE are glad to learn that an effort is about to be made to inquire into the various systems of registration in vogue in the different metropolitan hospitals. The subject was raised in these columns a few months ago by Mr. Howlett, and the commencement of a new medical year affords a favourable opportunity for renewed consideration of the subject. The present movement has been set on foot mainly by that gentleman, who has received assurances of support from the several hospital registrars. We are informed that a meeting will be held on Wednesday next, the 6th instant, at 8 P.M., at King's College Hospital, to consider the question; when it is hoped that many of those who have formerly held the office of registrar, and who may naturally be expected to take an interest in the matter, will attend, and that some definite action will be taken with a view to secure the introduction of a uniform plan to be adopted at all the hospitals.

PARASITICAL HÆMOPTYSIS.

JAPAN presents, apparently, a fruitful field to the pathologist. We lately chronicled the discovery of a new form of endemic fever by Professor Baelz of Tokio, and now, from the same observer, comes a description of a new form of hæmoptysis, of parasitical origin, the symptom of a disease which Baelz proposes to call "*gregarinosus pulmonum*." The disease is not only undescribed, but it is apparently unknown even to the native practitioners. Its chief symptom is hæmoptysis. Individuals, who are otherwise healthy, cough up bloody sputa, either continuously or at intervals, for many years. The hæmorrhage has no apparent connexion with phthisis or any other discoverable lung affection. Beyond the cough and expectoration, no morbid symptom, objective or subjective, is to be detected, even after the disease has lasted ten years. The affection appears to be a common one, for Baelz has already met with nineteen cases, twelve in the last year, and it is probable that thousands of Japanese suffer from it. All the cases hitherto seen have been in men, and for the most part between the ages of fifteen and twenty-five years. It is met with throughout the whole of Japan, but seems to be somewhat more frequent in the south. The sputa have a characteristic dirty-red aspect, and are thin. The red colour depends solely upon blood. A specific parasite is always to be found in it. This is met with in two forms: (1) as yellowish-brown, ovoid bodies of .13 mm. long, and .07 mm. wide. They have a double contour from a translucent wall .02 mm. thick, which, in different positions, appears greenish or reddish, and at the larger end is a kind of cover, at which the cyst opens. The contents consist of delicate jelly-like material, in which are embedded three or five aggregations of smaller bodies. The latter consist (a) of spherules about twice the size of a white blood-corpuscle, colourless, with sharp outlines. Around these spherules, and more or less enclosing them, is (b) a coarsely granular material, scattered through the jelly, and in it molecular movements may often be seen. When the spherules have left the cyst, they show for a time the same movements, and then become invested with the granular substance, and become motionless. The larger ovoid bodies are clearly

psorosperm cysts, and the young spherules seem to be psorosperms similar to those which Waldenburg and Eimer have found in the intestine and liver of the mouse and rabbit. Since these and other observers have ascertained that the bodies we call psorosperms are only a stage in the development of gregarinæ, Baelz proposes to call the disease gregarinosis pulmonum, and the parasite gregarina pulmonum, or, from its colour, gregarina fusca. No opportunity has apparently occurred for investigating the pathological anatomy of the disease.

PRISON DIETARY.

IN the recently issued second report of the Irish Prisons' Board which was established in 1877 under the provisions of the new Prisons Act, reference is made to the substitution of the English dietary for that formerly in use in Irish prisons. The medical officers do not, it appears, approve of the alteration, and have requested the Executive to submit the entire question to a competent medical commission. We learn with satisfaction, that since the report has been issued the Irish Government have agreed to the proposal and have appointed Dr. Robert McDonnell, Dr. MacCabe, Local Government Board Inspector, and Dr. Grimshaw, Registrar-General for Ireland, to carry out an inquiry into the present prison diet. We pointed out some time since, with regard to the new dietaries, that strong doubts existed as to their physiological sufficiency; and that the urban criminal accustomed to a liberal diet, and generally better housed than his rural brother in crime, finds prison life, as at present regulated, a severe strain on his vital powers, so that should there be any weak spot in his constitution, he breaks down under the pressure. We await with considerable interest the report of Drs. McDonnell, MacCabe, and Grimshaw, gentlemen thoroughly competent to carry out the investigation required in a satisfactory manner.

THE POPULATION OF THE EARTH.

NO stronger evidence of the world-wide influence of civilisation could be well urged than the possibility of the preparation of such approximately trustworthy statistics of the earth's population as are contained in the sixth issue of Boehm and Wagner's valuable publication, "*Die Bevölkerung der Erde*." The necessity for trustworthy vital statistics is gradually being acknowledged throughout the known world, and the area embraced by periodical census enumerations, as shown in a prefatory essay by Herr Nessman of Hamburg, is being constantly and rapidly extended. The joint authors of this valuable compilation, Boehm and Wagner, calculate and show the population of the world to be very nearly 1456 millions of persons, and nearly 17 millions more than it was at the time of the last issue of their publication nineteen months ago. It seems rather startling at first sight to hear that the population of the earth is increasing at the rate of nearly a million persons per month, but a little consideration shows that this is quite possible, since the rate of increase of population in most countries, of which we have trustworthy statistics, exceeds 1 per cent. per annum. Asia is said to contain considerably more than half the population of the globe, or 835 millions, Europe 316 millions, Africa 206 millions, America 95 millions, and Australia and Polynesia 4 millions. Bearing in mind the different areas of the continents, it is evident that America will long be able to absorb, to the advantage of itself and of all other nations, the surplus population of the rest of the world, even if it should exceed 12 millions per annum. In Europe the editors of this work naturally experienced the greatest difficulty in arriving at approximate figures for Russia and Turkey. The population of the Russian empire is given as 88 millions, of which 66 millions reside in Europe and 12 millions in Asia. The

Turkish empire is credited with 25 millions of population, including nearly 9 millions in Europe and rather more than 16 millions in Asia. There is admittedly much doubt as to the approximate accuracy of the estimate of the population of the Chinese empire at nearly 435 millions. The grounds upon which the population of the British possessions in India is estimated at 240 millions are far more worthy of trust; this will, however, be further tested at the census of the British empire next year. There can be no doubt of the increasing value and accuracy of succeeding editions of the "*Die Bevölkerung der Erde*," and if the information is not in all instances above suspicion, it may be readily admitted that no better standard on this large subject is available.

SUDDEN DEATH IN TYPHOID FEVER.

THE occurrence of sudden death in typhoid fever, without any hæmorrhage or perforation to explain it, has been variously accounted for. According to Dieulafoy it is always due to syncope, a reflex result of the intestinal lesion. But the accident has been met with after the intestinal ulceration has cicatrised, and also in typhus, in which there is no ulceration of the intestine. Hayem has ascribed it to organic changes in the heart, degeneration of the muscular fibres, but in some cases described the heart has been found to be healthy. Laveran attributed it to cerebral anæmia, and Huchard to a combination of this with cardiac degeneration. M. A. Marvaud has re-examined the question in the light of some cases which occurred last winter at Algiers. In this epidemic, thoracic complications were especially frequent. Twenty-two cases died out of ninety treated at one hospital, and in ten of these the heart presented ante-mortem clots. In four of these ten cases death was sudden; in three there was slow asphyxia with collapse, and in one death was preceded by free intestinal hæmorrhage. In the four cases of sudden death this occurred while the patients were making an effort. M. Marvaud believes that the pulmonary complications may have assisted in the production of the intra-cardiac coagula—first, by the mechanical obstruction to the circulation; and, secondly, by increasing the tendency of the blood to coagulate. In some cases death is instantaneous, and probably in these the intra-cardiac coagula interfere with the action of the valves, or plug the pulmonary artery. In other cases death follows asphyxial symptoms—quick breathing, anxiety, oppression, cyanosis, chilling of the extremities, small pulse, and collapse.

WOOLWICH AND SANDHURST.

THE annual reports of the Board of Visitors appointed by the Secretary of State for War to inspect the Royal Military Academy, Woolwich, and the Royal Military College, Sandhurst, have just been issued. Under the heading "*Sanitary*" the Visitors report that at Woolwich "the health of the students continues to be good," and at Sandhurst "the general health of the cadets for the past twelve months has been very good." But the documents appended to the reports do not bear out this favourable opinion. At Woolwich the course of instruction is divided into two terms, each comprising about 132 days; the intermediate periods constituting the vacations. The admissions into hospital during the year amounted to 218 in an establishment of cadets fixed at 195. These numbers give the annual proportion of admissions as 1545 per 1000, or not much less than double that occurring among troops in the United Kingdom. This certainly cannot be deemed satisfactory, and considering that the cadets are all young men who before joining have been examined by a Medical Board, and certified "to be free from bodily defects or ailments, and in all respects as to height and physical qualities fit for Her Majesty's Service," there would seem to have been either an unusual preva-

lence of disease, or a great laxity in the admissions into hospital, admitting of what would be considered malingering if it occurred among soldiers. The return for Sandhurst includes only the period from the middle of November to the beginning of July; deducting a month for Christmas and Easter vacations, there remain about 200 days of residence. The admissions amounted to 156 from an establishment of 300 cadets; they were therefore in the annual proportion of 951 per 1000, or considerably above that of the troops, but much under the proportion among the cadets at Woolwich. In both establishments the admissions for accidents, sustained chiefly at out-door games, and especially football, amounted to between one-fifth and one-fourth of the whole. The great excess at Woolwich occurred chiefly in measles, and in abscesses, ulcers, and boils, the cases of the latter group having been forty-two at Woolwich and only six at Sandhurst. A few years ago, in consequence of the prevalence of fever at Sandhurst, a careful examination was made of the sanitary condition of the college, and, if we remember rightly, the whole basement was found to be burrowed with cesspits. These were abolished, and the college thoroughly sewered. We are not aware of the state of the Woolwich Academy in this respect, but the large number of cases of abscesses, ulcers, and boils would suggest the necessity of an inquiry into this matter. The admissions into hospital, exclusive of those from accidents and injuries, occurring in the proportion of 1213 per 1000 in a body of healthy young men between the ages of sixteen and twenty, appear to call for an examination into the sanitary condition of the academy and its general management so far as that bears upon the health of the inmates.

THE CORTICAL CENTRE FOR MOVEMENTS OF THE FACE.

IN a recent issue of the *Progrès Médical*, M. Ballet records a case at La Salpêtrière confirmatory of the views of Charcot and Pitres as to the centre for the movements of the facial muscles being seated in the lower third of the parietal and ascending frontal convolutions. It is certainly very rare to meet with cases of facial paralysis arising from limited central lesions. The patient in this case was a woman seventy-one years of age, who for some time had been the subject of senile tremors. She was admitted into hospital with well-marked left facial paralysis, but with no impairment of motility of the limbs beyond a very slight degree of weakness in the left arm. Sensibility was unaffected. During the same day there appeared conjugate deviation of the eyes to the right, and the face became more strongly drawn to this side. The following day coma supervened, the eyes and head being strongly deviated to the right, and death took place three days later. Post-mortem examination showed a recent clot weighing five grammes in the cortex of the right cerebral hemisphere, occupying the lower part of the ascending frontal convolution and bounding the fissure of Sylvius. On section it was found to have destroyed the inferior frontal fasciculus, and to have encroached upon the corresponding parietal fasciculus, without, however, reaching deeply enough to involve the central grey nuclei. M. Ballet remarks that few cases hitherto published so clearly establish the seat of the psychomotor centre of the face, the majority of such cases being those of facial paralysis associated with brachial monoplegia, with lesions extending beyond the limit assigned to the face centre. In this case, however, the hæmorrhage and surrounding softening were limited almost entirely to the lower third of the ascending frontal gyrus, and had led to a facial "monoplegia" of the opposite side. The paresis of the arm, which increased slightly as the case advanced, was probably due to a slight extension of the hæmorrhage, and

to the pressure produced by this lesion upon the centre for the upper limb, which is in close contiguity to the facial centre.

COLOUR-BLINDNESS AND RAILWAY EMPLOYÉS.

WITH reference to the responsibility of railway authorities in the matter of guarding against colour-blindness among persons employed in moving railway trains, we are informed by the medical officer of one of the largest Indian railways that every European, Eurasian, or native who is appointed to out-door work on the open line has to pass not only a general medical examination, but a special examination with regard to his eyesight. This rule has been in existence for more than ten years, and consists of testing the ability of the candidate to distinguish many shades of colour by day, and coloured lamps by night. It is somewhat remarkable to hear that among the large number of employes appointed and examined during the past twelve years, only one European has been rejected for colour-blindness, whereas natives constantly fail to pass the test, many of them being afflicted with nyctalopia. This rare occurrence of colour-blindness among Europeans in India is in singular contrast to recent evidence of its prevalence in Europe.

IRREGULARITIES AT THE SMALL-POX HOSPITAL, KILMAINHAM.

DR. MACCABE, an Inspector under the Local Government Board for Ireland, on Monday last resumed an inquiry into certain charges brought against the management of this hospital. The charges were made by a former patient, named Lavery, who was admitted last May suffering from small-pox, and discharged cured on the 4th July. When leaving he expressed his thanks to the officials for the kindness he had received; but shortly afterwards complained to the guardians of the South Dublin Union relative to certain irregularities which existed at the hospital. Lavery asserted that in June he saw a wardman take from the hospital five shirts belonging to patients, which he pawned for drink; also that another wardman drank some brandy ordered for a dying patient and substituted water. He also accused the attendants of purloining the bread and meat, and disposing of them for their own advantage. These were very serious charges, but they were corroborated by another patient; and further, one of the attendants, a pauper inmate, acknowledged that it was a practice in the hospital for patients to give half their allowance of stimulants to the wardsmen for looking after them; and that he had known articles of clothing belonging to the patients to be pawned by the attendants. The inquiry has been adjourned, but sufficient evidence has been given to show that there is great room for reform in the management of the hospital.

A RATTLESNAKE BITE.

AN extraordinary account of recovery from a rattlesnake bite has been published in *Land and Water*, by Dr. Arthur Stradling, of H.M.S. *Elbe*, who has apparently been making some experiments, no doubt well intended, but most unwisely ordered, in the endeavour to discover an antidote. He had arranged for the snake—a small *Crotalus horridus*, about eighteen inches long—to bite his right arm above the wrist, and he grasped the creature with his left hand, protected by a thick leather glove. The snake, however, managed to wriggle through his fingers, and bit him on the back of the left forearm, leaving one of its fangs sticking in the wound. Putting it back in the box, he picked out the bit of fang with a pair of forceps and sat down to watch the result! This was at one o'clock in the morning. He had ligatures, ammonia, brandy, and nitric acid at hand in readiness; but the value of the caustic and ligature could not

be great, since he waited for the symptoms of absorption before applying them. He went on waiting for four hours, until 5 A.M. Then he noticed that the lymphatics higher up the arm were swollen and inflamed, and almost at the same moment he became aware of light-headedness, and of a burning sensation traversing his whole frame. There seemed to be great vascular and mental excitement, yet his temperature was down to 96°. After this evidence of absorption he applied the nitric acid to the bite, but almost immediately became irresistibly drowsy, and then unconscious. At 11 A.M., ten hours after the bite, he was found insensible, pale, pupils contracted, feet and legs cold, but with an axillary temperature of nearly 100°; the intercostal muscles, arms, and legs were paralysed; the diaphragmatic respiration was irregular. A medical man on board sucked the bites and cauterised them freely, and gave ether and ammonia every half hour. There was no movement of the body until three in the afternoon, when a tetanic spasm occurred, followed by hiccough and twitching of the muscles about the shoulders. The experimenter then recovered consciousness, slowly regained power over the limbs, and slept for twelve hours. After this he was well, except for prostration. It is hardly possible to conceive an experiment made under more reckless conditions—an experiment with a rattlesnake in solitude, in the middle of the night, and by an observer apparently ignorant of the rapidity with which the action of the poison, once set up, develops. The result teaches nothing new, and it is difficult to understand what, under the circumstances, could be learned from it.

DEATH FROM CHLOROFORM.

WE have to regret another case of death from chloroform inhalation. It took place at the West London Hospital on September 21st. The case was one of epulis of the upper jaw, and the anæsthetic was being carefully administered by Mr. Johnston, the house-physician. The patient had just come under the influence of the anæsthetic when the heart's action suddenly became arrested. The tongue was drawn forward, and artificial respiration, galvanism to the carotid region, and the hypodermic injection of atropine were had recourse to; but the efforts to restore animation, although energetically carried out, proved unavailing.

PERINEPHRITIS IN CHILDREN.

A VERY interesting paper on this subject has been published by Dr. V. P. Gibney, of the Hospital for the Ruptured and Crippled, New York. The paper contains a clinical record of fifteen cases, in addition to a previously published series of thirteen cases, which have appeared in various American journals, by the same author. The present paper is a reprint from the *Chicago Medical Journal and Examiner*. All the cases recovered perfectly, except one in which slight lameness remained. Dr. Gibney maintains that more than ninety per cent. of cases reported as cases of hip disease and cured without lameness or deformity never have been cases of hip disease at all, but cases of perinephritis, perityphlitis, periartthritis, primary traumatic periostitis, of various neuroses of the hip, of subacute rheumatism about the hip, or of acute primary synovitis of the hip; all of which are insignificant as compared with true hip disease, which is chronic and slowly progressive. The clinical pictures in the fifteen cases are very clear, involving generally the following symptoms—rigor, fever, lancinating pains in the lumbar region, constipation, spasm of the psoas muscle, the gait like that of hip disease, and swelling in the ilio-costal space when the pain becomes excruciating. The thigh can be flexed and rotated, but not fully extended without pain; generally the thigh is found flexed. The disease may terminate either in resolution or suppuration. In sixteen cases there was suppuration, in twelve there was not. The average duration of the disease

was three and a half months. In nineteen no exciting cause could be found; in eight a contusion, a strain, or a fall, and in one a nephritis seemed the starting-point. The age of the patients was from one to fifteen years. The chief treatment was rest, fomentations, and early evacuation of pus. The paper is an excellent specimen of clinical and discriminating work. That one medical man should encounter twenty-eight cases is enough to induce medical men to be careful and hopeful in their examination of acute maladies like those affecting the hip-joint.

THE Science College in Birmingham, founded by Sir Josiah Mason, is to be opened to-day (Friday). By its foundation deed the institution is established to provide instruction in mathematics, physics, chemistry, the natural sciences, especially geology and mineralogy, botany and zoology, physiology, with special reference to the laws of health, and the English, French, and German languages. The scheme is also sufficiently elastic to admit of instruction being given in such other branches of knowledge as may properly be included in the term "science," mere literary education being excluded. The course of instruction is designed to prepare students for the degrees of B.Sc. and D.Sc. in the London University.

AT the Quarterly Court of the President and Managers of the Royal Infirmary, Aberdeen, recently held, it was resolved that it be remitted to the Committee of Management to consider and report, after consultation with the medical staff, first, as to the expediency of appointing as resident assistant to the hospital medical staff only such as possess a degree or diploma, or have passed all the examinations for the same; second, as to any changes in the existing regulations of the Infirmary which they would recommend to be made for this purpose. Such report to be submitted to the quarterly meeting of managers.

BY the death of Dr. Wilms, surgeon-general, of Berlin, in his fifty-eighth year, surgery has suffered a great loss. The immediate cause of the lamentable event appears at present somewhat doubtful, it having, on the one hand, been attributed to septic poisoning contracted during the performance of an operation about three months ago, and on the other to the bursting of a bloodvessel; in either case, however, the comparatively early death of the distinguished surgeon must be regarded as another illustration of the perils which environ the practice of the healing art.

MR. G. S. V. WILLS, principal of the Westminster College of Pharmacy, at the opening of the session of the College a few days since, expressed the opinion that the only remedy for the "co-operative society" evil in connexion with dispensing would be the introduction of a new Pharmacy Act. He believes this will be forthcoming before long.

A CORONER'S JURY, at an inquest on a woman found dead on the steps of the Poplar workhouse, expressed their opinion that there was gross neglect on the part of the workhouse authorities, and that no pauper inmate should be employed as night watchman.

THE Hospital Saturday movement has been commenced at Gainsborough, and the first collection has resulted in the creditable sum of £95 4s. 5d., £60 of which has been paid to the Lincoln County Hospital, and £30 to the Leeds Infirmary.

THE Earl of Carnarvon, having consulted Dr. Graham of Madeira, during a visit which that well-known physician has recently paid to this country, has determined to spend the winter in the island.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

St. Giles' District, London (population, 1871, 53,429).—Mr. Lovett's report for 1879 has its chief interest for the evidence it affords of the increasing efficiency of the control exercised by the District Board of Works, and of the supervision maintained by the medical officer of health over this district of central London—a district of which the almost incredible difficulties of sanitary administration rest even more with the character of much of its population than with the unwholesome courts and alleys in which the mass of its more destitute inhabitants are housed. In 1879 St. Giles had a death-rate (22·5 per 1000 population) below the general death-rate of the metropolis (23·3); and with regard to several principal zymotic diseases, the prevalence of which in earlier days formed a deplorable characteristic of the district, the rate of mortality was 2·4 per 1000, as compared with 3·2 in London generally.

The most interesting part of Mr. Lovett's report for the particular year is an account given of an outbreak of true typhus. The disease had been absent from the district since the year 1874, when in the summer and autumn of 1879 it appeared again. The malady showed itself in its *old haunts* in the district, haunts which, happily for the district, have now been swept entirely away by clearances of unhealthy areas effected by the Metropolitan Board of Works under the Artisans' Dwellings Act, 1875. There were two groups of cases, one beginning in August, the other in October, both more or less connected with the autumn movement of hop-pickers. The cases as described by Mr. Lovett present many points of interest with reference to sanitary administration. The reappearance of the disease in its old accustomed haunts—haunts hideously characteristic of the worst form of dwellings of the metropolitan poor and migratory labouring classes, and now swept away. Would that all similar localities could be dealt with in like fashion in the metropolis and elsewhere! The close relation between the groups of cases and the hop-pickers' migration indicates that we want to know much more than we yet know of the conditions under which hop-picking is carried out in the south-eastern counties. It is highly probable, from Mr. Lovett's story, that typhus existed among the hop-pickers of Cobham in October, 1879. The difficulty of dealing with cases of infectious disease, in view of arresting the spread, among migratory people such as the hop-pickers, is most instructively illustrated by these cases. We read of one case of typhus conducted by a brother to Gravesend, and placed there in a train and sent to London. Shortly after the brother himself is seized. He is sent in a fly to Gravesend, then proceeds by train to London, and makes his way to St. Thomas's Hospital, where he died of the fever.

Pembroke Urban Sanitary District (estimated population, 15,000).—Dr. Protheroe Saer reports a lower mortality in this district during 1879 than had occurred in any of the several years that the Public Health Act has been in force. The death-rate was 16·79 per 1000 of the estimated population, and the birth-rate 32·8. Diseases of the heart and blood-vessels stood first in order among the causes of death; phthisis pulmonalis second; bronchitis, pneumonia, and pleurisy third, and infantile convulsions fourth. Dr. Saer discusses, with a view of showing to what extent these causes of death may have been influenced in their incidence by local conditions of unwholesomeness which are removable, and it is obvious these are not wanting in Pembroke. He comments also, in regard to infantile convulsions, on the absence of due care in the nursing of infants too commonly observed. The mortality from the chief zymotic diseases was very low in Pembroke during 1879, the total number of deaths being only 15, as compared with an annual average of 58 during the five preceding years. Dr. Saer attributes this marked decline in the mortality from these diseases to the measures adopted for their prevention from time to time by the Sanitary Authority. We shall be glad if this prove to be the case, for there appears to be still much to be done in the

way of sanitary amendment in Pembroke, and we shall hope, the Sanitary Authority continuing its efforts, to find even greater declension in the mortality from these diseases, and corresponding falling off in the general mortality and in the sickness of the place. Indeed, Dr. Saer looks forward (somewhat prematurely, we think) to a possible immunity from the diseases in question when certain measures of drainage and water-supply which have been determined upon by the Sanitary Authority are carried out. But pending these greater measures there is evidently much detailed work to be done in Pembroke with regard to nuisances. Indeed, the impression left on our mind by the report is that the Sanitary Authority is negligent in the performance of its duties as to nuisance prevention, which if not efficiently carried out may frustrate the best schemes of water-supply and drainage, so far as the public health is concerned. At least so we interpret the references to nuisances in this report, which have been reported more than once by the medical officer of health.

THE METROPOLITAN WATER-SUPPLY.

Lieut.-Col. Bolton's report on the state of the metropolitan water-supply for August shows that the water of the Thames at the various intakes of the companies was bad from the 1st to the 3rd of the month, when it became pure, and continued so to the 31st. The water in the river Lea was also good during the greater part of the month. The water of the Thames, however, although good, was slightly coloured by organic matter, principally arising from vegetation brought down by the flood-waters in the early part of the month. Filtration failed to free the water from the colour referred to, but it is stated to have been generally efficient, so far as freedom from turbidity is concerned. Dr. Frankland's report states that the water delivered by the water companies from the Thames was of "very bad quality," and "quite unfit for dietetic purposes, owing to the large quantity of organic matter which it contained." The water from the Lea, "though efficiently filtered, was no better than Thames water"; but the deep-well water "was of its usual excellent quality for dietetic purposes," and that sent out by the Colne Valley Company was also excellent.

A SANITARY SPASM: EDMONTON.

Last week we had to record proceedings of the Edmonton Local Board against a builder for using improper materials for mortar, the bye-laws of the Board notwithstanding. This week we are glad to have to record further proceedings of this Board against builders for infringement of their bye-laws. Two firms were summoned before the magistrates, and in both cases fined the full penalty, for having disregarded the bye-laws of the Board with reference to the foundations of certain houses. The Local Board wished to withdraw the cases on a promise of amendment, but the magistrates very properly would not allow this. It is not easy to understand how this unusual activity of the Edmonton Local Board has been brought about. Edmonton would have escaped a heavy penalty in badly-constructed buildings if this activity had been displayed some time ago, when there was quite as great need for it as now. But better late than never; and let us hope that this is not a mere passing spasm. With everything in its favour, by the negligence of the Local Board, Edmonton has now for several years been given up as a prey to cheap builders.

THE SEWERAGE OF KANTURK.

The Local Government Board for Ireland have recently been in communication with the Kanturk Board of Guardians with reference to the sewerage of this town, their attention having been directed to the matter by information received from one of the residents. Their correspondent stated that a sewer coming from the workhouse discharged its contents in the centre of the town, and that it was a nuisance dangerous and abominable, containing for the most part the filth from a hospital in which typhus fever of a malignant type is at present raging. Also that the water in the river, which is contaminated by the sewage, is used by people in the vicinity for washing and other domestic purposes, and that some bakers use it in the process of preparing their bread. The river, however, has several other sewers passing into it, one being from a public cemetery, and mostly all discharging into the river invariably at the nearest available point. Further, that the entire sewerage is bad, and that the inhabitants have not been compelled to

make efficient connecting-drains between their houses and the main sewers. This was a strong indictment against the guardians as the sanitary authority; but we regret to find that they admitted all the statements made, and evaded the difficulty by requesting the Local Government Board to send down their engineering inspector to report on the present system of sewerage of Kanturk.

POLLUTION OF THE THAMES.

The Corporation of Windsor were summoned before the Petty Sessions held in that town last week by the Conservators of the Thames for passing into the river sewage imperfectly purified. The Corporation effects the purification of the sewage of the town by Professor Hillé's process, but at the particular time submitted to the consideration of the Court it was held that the effluent from the purification works conveyed to the river was not such as to render it fit for mingling with the stream; and the Court fined the Corporation £5, allowing £5 5s. as costs. We are glad to note this indication of activity on the part of the Thames Conservators in carrying into effect their powers for securing greater freedom from pollution of the river.

SLAUGHTER-HOUSES AND COW-SHEDS IN THE METROPOLIS.

The Kensington Vestry have printed two reports—one by Dr. Dudfield of an inspection of the licensed slaughter-houses in their district, another by Mr. Wm. Bouteher, the chairman of the General Purposes Committee of the Vestry—of an inspection by the Committee of the licensed cow-sheds. In both inspections defects and negligences were discovered which indicate that the disservice of the sanitary administration of slaughter-houses and cow-sheds from the ordinary sanitary administration of a district is much to be regretted. The imposition of this duty upon the Metropolitan Board of Works does not seem to secure either efficiency or certainty in its performance, and complicates the sanitary administration of a district.

At a meeting of the Widnes Local Board the chairman, referring to the prevalence of fatal diarrhoea among young children in the district, made the following statement:—"The habits of the people were such that he really did not feel much surprised at the extent of such disease. In cases where fruit and vegetables had been ordered to be destroyed, and had been thrown into the ashpits at the back of shops by the occupiers, no sooner had they been emptied than shoals of children descended upon the places, and ate both the vegetables and fruit with avidity; and not only so, but offal which they picked out of such places."

The chairman does not appear to have understood that this statement convicted the Local Board of the grossest negligence with reference to the removal and deposit of refuse.

Dr. Blaxall, of the Local Government Board, met the Sanitary Authority of Newtown, Montgomeryshire, a few days ago, and conferred with them on the measures to be taken to arrest the spread of scarlet fever, of which a serious outbreak has occurred in the district.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Notwithstanding the recent moderate temperature, the rate of urban mortality declines but slowly. In twenty of the largest English towns, estimated to contain in the middle of this year seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5204 births and 3466 deaths were registered last week. The births exceeded by 69 and the deaths by 191 the average weekly numbers during 1879. The deaths, however, showed a further decline of 75 from recent weekly numbers, and were equal to an annual rate of 24.1 per 1000, against 25.4 and 25.0 in the two preceding weeks. The lowest death-rates in the twenty towns last week were 20.5 in London, 21.6 in Plymouth, 21.7 in Oldham, and 21.8 in Birmingham. The rates in the other towns ranged upwards to 32.9 in Liverpool, 35.3 in Sunderland, 35.9 in Hull, and 37.7 in Norwich. The high rates in these four last-mentioned towns were mainly due to excessive zymotic fatality. During the twelve weeks ending last Saturday, the death-rate in these twenty towns averaged 23.4 per 1000, against 24.0 and 18.3 in the corresponding periods of 1878 and 1879.

The deaths referred to the seven principal zymotic

diseases in the twenty towns, which had been 1190 and 1009 in the two preceding weeks, further declined to 9.2 last week; of these, 611 resulted from diarrhoea, 119 from scarlet fever, and 72 from other forms of fever, principally enteric. The annual death-rate from these seven diseases averaged 6.3 per 1000 in the twenty towns; it ranged from 3.5 and 3.7 in Plymouth and London, to 12.6 and 17.0 in Salford and Norwich. Diarrhoea fatality showed a further general decline last week; the annual death-rate from this disease did not exceed 2.0 in London, while it averaged 6.4 in the nineteen provincial towns. Among the nineteen towns, the diarrhoea death-rate ranged from 3.5, both in Portsmouth and Plymouth, to 8.9 in Salford and 9.8 in Hull. Scarlet fever showed the largest proportional fatality in Norwich, Sunderland, and Bristol. Enteric fever showed a generally increased fatality last week, and exceeded that which prevailed in any previous week this year; the highest death-rate from this disease occurred in Norwich, Salford, Portsmouth, and Leeds. Small-pox caused five more deaths in London, but not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 104 and 116 at the end of the two preceding weeks, declined again to 105 on Saturday last; 6 new cases of small-pox were admitted to these hospitals during the week, against 7, 13, and 27 in the three previous weeks. The Highgate Small-pox Hospital contained 7 patients on Saturday last.

The deaths referred to diseases of the respiratory organs in London, which had been 124 and 153 in the two preceding weeks, further rose to 174 last week, but were 4 below the corrected weekly average; 107 resulted from bronchitis and 41 from pneumonia. The annual death-rate from lung diseases was equal to 2.5 per 1000 in London, against 3.9 in Liverpool.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 18.9 per 1000, against 18.2 and 20.3 in the two preceding weeks; this rate was no less than 5.2 per 1000 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 11.7 and 18.1 in Perth and Dundee, to 23.1 and 24.4 in Leith and Paisley. The fatal cases of the seven principal zymotic diseases in the eight towns were 153, against 129 and 163 in the two preceding weeks; they included 53 from diarrhoea, 45 from scarlet fever, 23 from diphtheria, 16 from whooping-cough, 9 from fever (principally enteric), 7 from measles, and not one from small-pox. The annual death-rate from these seven diseases averaged 6.2 per 1000 in the eight towns, and was almost identical with the rate from the same diseases, 6.3, in the twenty English towns. The zymotic death-rate in the Scotch towns last week ranged from 0.0 and 2.1 in Perth and Paisley, to 6.7 and 8.9 in Glasgow and Leith. The fatal cases of diarrhoea in the eight towns, which had been 63 and 69 in the two previous weeks, declined to 53 last week, and were equal to an annual rate of 2.1 per 1000, while in the twenty English towns the diarrhoea death-rate averaged no less than 4.2. The largest proportional fatality from diarrhoea in the Scotch towns occurred last week in Dundee and Leith. The deaths from scarlet fever in the eight towns, which had been 18, 22, and 36 in the three previous weeks, further rose last week to 45, of which 25 occurred in Glasgow, 16 in Edinburgh (against 8 and 15 in the two previous weeks), and 3 in Leith. The largest proportional fatality of scarlet fever last week was recorded in Edinburgh and Leith. The 9 deaths referred to fever showed a marked decline from the number in the previous week, and included 6 in Glasgow. The 23 deaths from diphtheria considerably exceeded the numbers in recent weeks; 11 were returned in Glasgow, 7 in Dundee, and 4 in Edinburgh. The deaths attributed to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) were 68 in the eight towns last week, against 65 and 61 in the two preceding weeks; the annual death-rate from these diseases was equal to 2.7 per 1000 in the eight towns, against 2.2 in London.

HEALTH OF DUBLIN.

The excessive mortality in Dublin showed but a slight decline last week. The annual death-rate in the city, which had been equal to 34.7 and 39.3 in the two preceding weeks,

was again equal to 38.5 last week. During the past twelve weeks of the current quarter the death-rate in the city has averaged no less than 34.5 per 1000, against 20.5 in London and 20.8 in Edinburgh. The 232 deaths in Dublin last week included 71, or nearly 31 per cent., which were referred to the seven principal zymotic diseases, showing a decline of seven from the number returned in the previous week; 44 resulted from diarrhoea, 14 from scarlatina, 5 from whooping-cough, 4 from measles, 2 from small-pox, and 2 from fever. The annual death-rate from these diseases was equal to 11.8 per 1000 in Dublin, whereas it did not exceed 3.7 in London and 6.6 in Edinburgh. The 44 fatal cases of diarrhoea in Dublin exceeded the number returned in any previous week of this year, and were equal to an annual rate of 7.3 per 1000, while the death-rate from diarrhoea in London did not exceed 2.0. The deaths from scarlet fever showed a considerable increase upon those returned in the two previous weeks; while those from measles, whooping-cough, and fever were less numerous. The proportion of infant mortality continues to show a marked excess in Dublin.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE EXETER CONGRESS.

The Congress of the Sanitary Institute at Exeter may be regarded as, perhaps, the most successful of the several congresses in which that youthful body has indulged. In the principal addresses delivered, the President (Earl Fortescue) avoided the mistake of bringing matters home to the feelings of the Congress and of Exeter people by devoting his attention to matters of sanitary history and the municipal government of London. Mr. Rawlinson, C.B., went wide afield for illustrations of sanitary progress and stagnation, but made amends by giving us three useful degrees of sanitary comparison, teaching us that Belgravia is bad, Whitehall is worse, and Somerset House worst of all. This should be interesting to architectural students wishful to penetrate the mysteries of construction in its sanitary aspects. Dr. B. W. Richardson startled the Congress with a brand-new view of woman as the sanitary teacher and administrator, "because it was an office which man could never perform"; but, alas! in the classical example he held up for imitation (the wife of Ischomachus the Jew), it appeared that she was instructed by her husband. He failed to reconcile the difficulty, that if man could not perform, how could he teach? Professor de Chaumont discoursed on the signification which the Institute attached to the term "preventive" or "public medicine," and capped the story of the wife of Ischomachus with the more familiar stories of Hygeia and of Minerva as deities of health.

THE UNHEALTHINESS OF PUBLIC INSTITUTIONS.

Mr. Henry C. Burdett read a further paper at the Exeter Congress on the unhealthiness of public institutions, illustrating his subject by three examples of comparatively new buildings, a hospital, a convalescent institution, and a lunatic asylum. In each of these cases the greatest ignorance had been displayed by the architects in the sanitary arrangements of the several buildings, and soon after their occupation this was made obvious by the manifestations of disease among the inmates, and costly reconstructions had to be entered upon. Mr. Burdett suggested a deputation from the Congress to the Local Government Board on the subject. But he had previously said, and his statement was confirmed by Mr. Robert Rawlinson, that that Board is itself a victim in its own office of the evils he denounced. If the Local Government Board is unable to protect itself and its officers against architectural blunders, how will it be able to protect others?

MORTUARIES.

Mr. Burdett communicated also to the Congress a very instructive paper on Mortuaries in their public-health aspects. This paper gave an excellent summary of the question in this country, both historically and legislatively; and contained in an appendix a statement of the existing public-health provision, so to speak, of mortuaries, both in the metropolis and the provinces. Mr. Burdett made several valuable suggestions to meet the difficulty of providing a mortuary where the local authority is unwilling to act.

SANITARY PROTECTION.

A Sanitary Protection Association has been established in Newport, Rhode Island, on the basis of the Society started in Edinburgh by the advocacy of Professor Fleaming Jenkins, and having for its object the mutual sanitary insurance of its members. It seeks also, after the fashion of the Tottenham Sanitary Association, to incite the municipal authorities to give greater regard than they appear yet to have given to the general sanitary welfare of the place. The Association proposes to provide its members, at moderate cost, with such advice and supervision as shall insure the proper sanitary condition of their own dwellings; to enable members to procure practical advice, on moderate terms, as to the best means of remedying defects in houses of the poorer class in which they are interested; and to aid in improving the sanitary condition, and consequent good repute of the city, by following such course as, in the opinion of the Council, may seem calculated to promote this object. A novel feature of the operation of the Association is that one of its members has placed at its disposal one hundred dollars, half of which is offered as a prize to the person, not the owner of the house occupied, who shall put his or her premises in the most satisfactory condition by Jan. 1st next, and keep them so until June 1st; and half to the house-owner who shall do the most between Sept. 1st, 1880, and June 1st, 1881, towards improving the sanitary condition of any occupied dwelling.

DIPHTHERIA IN RUSSIA.

It is reported from Poltava that the measure which has been found most efficacious in arresting the spread of diphtheria has been the disinfection of infected houses with burning sulphur. But the peasants, supported by the priests, object to this process. They regard the measure as impious and contrary to the rites of religion. Moreover, they hold it to be foolish. They can understand treating the patient medically, but not the house. "Cure the sick if you like," say they, "but what have our houses to do with the sickness?" Again, they are apathetic as to the deaths of children. "Many die," some exclaim, "but see how many more are left." The peasantry in some places have resisted the intrusion of a "disinfectant," and in one village they seized upon a sister of charity, who was with difficulty saved by the intervention of the police from being burnt alive, a fire having already been kindled for the purpose.

The dearth in Samara has been followed by diphtheria, which is reported to have spread widely in the province.

YELLOW FEVER.

The 22nd September was given up to rejoicings in Memphis because the city had escaped this summer from the ravages of yellow fever. Triumphal arches were raised, and the civic societies and trades marched through the chief streets, forming a procession three miles in length, large crowds assembling to witness it and take part in the general gladness. The governors of Kentucky, Tennessee, and Arkansas were also present. Although the form which the public rejoicing assumed may appear somewhat strange to the English reader, it is impossible not to sympathise with it and the feeling from which it sprang.

HOW DISEASES ARE SPREAD.

Two men, patients at Kilmainham Small-pox Hospital, were summoned at the instance of the South Dublin Union Guardians last week for having left the hospital for an entire day while in the convalescent stage of the disease, and fined in the mitigated penalty of forty shillings each.

At a public meeting held on the 13th of September, at Westgate-on-Sea, a committee was appointed, to be called the "Westgate-on-Sea Sanitary Association," for the sanitary protection of the visitors and inhabitants of this rising health-resort. Professor Erasmus Wilson, F.R.S., was appointed chairman; Mr. W. Orchardson, R.A., vice-chairman; and Mr. Arthur Flint, L.R.C.P., hon. sec. and treasurer.

The want of a public mortuary in Mile-end New Town was painfully manifest last week, when a coroner's jury, on proceeding to "view," found the body lying in a small squalid room, in which were sleeping three persons, who had to be roused to enable the "twelve" to discharge their nspectorial function.

It is proposed to build a new water conduit in New York, whereby the supply will be augmented from 100,000,000 gallons per day to 250,000,000 gallons. The estimated cost is 10,000,000 dollars.

A committee has been appointed by the Holborn Board of Guardians to inspect the disused Small-pox Hospital at Hampstead, with a view to acquiring the building for workhouse purposes generally.

THE GENERAL BOARD OF HEALTH, EGYPT.

THE General Board of Health, Egypt, is a body of which we rarely hear in this country except when, by the imposition of quarantine restrictions on ships in Egyptian ports or passing through the Suez Canal, it excites the ire of English shipmasters and shipping firms. The Board consists of two divisions, one of which concerns itself with the internal sanitary arrangements and service of Egypt; the other, known as the International Sanitary Council, controls those sanitary arrangements, such as the administration of quarantine, which affect other countries in their relationship with Egypt. On this Council sit delegates of all the Powers which have representatives at the Khedive's Court. A similar council forms part also of the General Board of Health of the Ottoman Empire, and the Egyptian Board is believed to have been constituted after the pattern of the Turkish Board. There is some obscurity about the functions of these councils. It is believed that when first established the duties of the several delegates was simply to watch the material interests of their respective countries as liable to be affected by the action of the General Board, particularly in the imposition of quarantine upon their shipping and the crews trading to one country or the other, both ships and crews being at this time regarded as extra-territorial. But be this as it may, the international councils of the two boards appear to have acquired or assumed functions very different from those presumed to have originally attached to them, and the Egyptian Board at least, according to our contemporary the *Egyptian Gazette*, is regarded locally as a body constituted "to prevent the spreading, through Egypt, of epidemics to Europe from the East." We have heard something of this sort before, and have a suspicion that the notion, if not originated, took form at the International Sanitary Congress of 1866, when the Egyptian General Board of Health was regarded as the advanced sanitary post for protecting Europe from the invasion of cholera by way of the Red Sea route and the Holy Land of Mahommedanism—the Hedjaz. At any rate, France, Italy, Greece, and other maritime countries of Europe partial to quarantine, seem to hold the view of the functions of the Egyptian International Sanitary Council expressed by the *Egyptian Gazette*, and, so far as those functions relate to quarantine, that view may be colourable. But even as regards quarantine, it would appear that the practice of the Council falls miserably short of its assumed or professed international functions. For our contemporary, representing English opinion in Alexandria, and in reality in Egypt generally, does not hesitate to affirm that the quarantine maintained under the Council's authority is more injurious to the persons quarantined than beneficial to Egypt or to Europe at large. In fact, it is averred that such danger as Europe has to guard against from disease travelling by way of Egypt is a danger not to be controlled by measures of quarantine, but depending upon the generally insanitary state of the country; and our chances of protecting ourselves from this danger must be proportionate to the extent we can influence the Egyptian Government to adopt measures of internal sanitary reform. It would seem that the foreign delegates of the International Council have not hesitated to interest themselves in the internal sanitary arrangements of Egypt, but our contemporary urges that they and the Council, as a Council, should have a voice in them. It may recommend, but has no power or means to enforce its recommendations being carried into effect. "Till the International Sanitary Council has a thoroughly effective control over the whole of the hygienic arrangements in Egypt," says our contemporary, "we cannot hope for any reasonable security against the ravages of an epidemic, and Europe has no protection whatever against the importation of disease through

Egypt." In other words, the International Council should be merged in the General Board of Health, the board acting as a whole in all sanitary matters, whether home or international.

Underlying this suggestion is the distrust of the efficiency of any sanitary measures which may be adopted in Egypt except these are controlled by Europeans. This is an old story. France has particularly urged the necessity of all the important administrative posts in the quarantine service being filled by Europeans, if the quarantine service is to be properly performed. The *Egyptian Gazette* sees a like necessity in the general sanitary administration of the country. The question of merging the International Sanitary Council in the General Board of Health is a diplomatic one; but the appointment of efficient officers rests with the Egyptian Government. This has not shown itself unwilling to take advantage of skilled medical European talent; and it has among the native medical practitioners men who have been trained in European schools, and who have the highest qualifications. It may be questioned whether these men are in number sufficient to fill all the administrative sanitary posts which it is desirable should be filled by individuals possessing high qualifications, and it would no doubt be well to supplement them by high-class men of other than native origin. To what extent this may be a matter in which foreign governments think themselves called upon in the interest of Egypt, of Europe, or of the European residents in Egypt, to advise the Egyptian Government, we do not pretend to say, but we have no doubt that a larger importation of European skill, medical and other, in the sanitary administration of Egypt, and the admission of the delegates of foreign representatives to the councils of the General Board of Health on the general sanitary administration of the country, would be of immeasurable benefit to Egypt, and so far as the sanitary state of that country concerns the Continent, to Europe also.

Correspondence.

"Audi alteram partem."

THE IMMEDIATE TREATMENT OF STRICTURE OF THE URETHRA.

To the Editor of THE LANCET.

SIR,—In your journal of Sept. 18th Mr. Holt states that he has not replied to my criticisms on his operation, as he considers I am "perfectly incompetent to form any opinion as to the value of the operation and its results," my experience being limited to a few cases. When I mention that I was for *five years* attached to the Westminster Hospital as Demonstrator of, and afterwards Lecturer on, Anatomy, and that I witnessed the operations performed by Mr. Holt and his colleagues, I am afraid your readers will not accept Mr. Holt's explanation. Mr. Holt and his colleagues certainly convinced me, in the most unequivocal way, that the operation was *not* "free from every danger," as stated by Mr. Holt in his book. We do not as yet know how many deaths have occurred after the operation, as only a few have been published; but on looking over a list I have of fatal cases of Mr. Holt's operation, I find I have credited Westminster Hospital with five deaths, only one of which, I believe, ever appeared in print—a fact which I commend to Mr. Lane's notice. When Mr. Wood stated that he had seen two fatal cases at King's College Hospital under Mr. Partridge, he forgot to mention that Mr. Henry Smith had had a death, and Sir Wm. Fergusson one also, I believe; at all events, that eminent surgeon abandoned the operation on account of its *fatal results*. The operation was tried in Paris, and discarded on account of the deaths and unsatisfactory results which followed it. In America Gross, Otis, Mastin, and others, have abandoned it in favour of internal urethrotomy, for reasons which they have stated. In this country Sir H. Thompson, Mr. Wood, Mr. Croft, Mr. B. Hill, Mr. Annandale, Mr. Coulson, Mr. F. Jordan, and Mr. Lund all practise internal urethrotomy in preference to the so-called immediate treatment, which they have given up. In London the operation is now only performed in some three hospitals out of fourteen. It is only

suitable for *selected cases*, as proved by its advocates, who excuse it for killing a man if he had "false passages" or "albuminous urine." Holt's operation is fatal if there be renal disease, in proof whereof I need only refer to the case of a man "with a dropsical affection," who, for urgent reasons, was submitted to it by Dr. Lyster. Internal urethrotomy, on the contrary, is not barred by such complications, as proved by a patient of Mr. Symes', of Briton Ferry, upon whom I performed it, who was suffering from a desperate traumatic stricture, œdema of the legs and scrotum, and albuminous urine. The man wrote to me not long ago to say that he was well, at work, and able to pass his instrument. As regards the *permanent results* of each operation, I can state, from a personal examination of patients, in hospital and private practice, years after they had been operated on by Sir H. Thompson, Mr. Holt, Mr. B. Hill, Mr. Heath, and the late Mr. J. D. Hill, that the tough, irregular, often non-dilatable cicatrices following Mr. Holt's operation, contrasted very unfavourably with the soft, supple, dilatable splices inserted by Sir H. Thompson by means of internal urethrotomy. I have to thank Mr. Christopher Heath for kindly proving that, even in his able hands, the rate of mortality following Mr. Holt's operation was *more than double* that of internal urethrotomy as practised by his colleagues.

I remain, Sir, yours, &c.,

Portman-square, Sept. 28th, 1880.

W. F. TEEVAN.

To the Editor of THE LANCET.

SIR,—I had been looking forward for some reply to the criticisms made upon Mr. Barnard Holt's method of treating stricture of the urethra, and have, therefore, read with pleasure the letters from Mr. Holt and others in THE LANCET of September 18th and 25th.

My own personal experience of the operation has hitherto been very favourable, though not extensive, but I was led to adopt it by the praises I heard bestowed upon it by two such good practical surgeons as the late Mr. De Morgan and the late Mr. Maunder, whose estimate of the operation may have interest and value for many of your readers. Anyone who knew Mr. De Morgan well must remember how difficult it was to get a decided opinion from him, and how well matured his judgment was on subjects upon which he expressed himself unhesitatingly. Upon the splitting operation of Mr. B. Holt I heard Mr. De Morgan on more than one occasion speak in the highest terms, and he used to say that he had never known any serious danger arise from it. Mr. Maunder, too, thought most favourably of the operation and practised it frequently and successfully.

To the condition of the urethra which may obtain many years after the operation the following case testifies:—A gentleman, lately home from India, who admits to having lived a fast life, and tried himself in many ways, is now under my care for hydrocele. He tells me that eleven years ago he was operated upon by Mr. Barnard Holt, and that for eight months afterwards he continued to pass a large-sized bougie at intervals. From that time till the present he has never passed any instrument at all, and when asked if he had since had any contraction of his stream, or other sign of returning stricture, he replied in a surprised tone, "No! I was quite cured eleven years ago, and have had nothing whatever the matter with my water since."

Such a result may be equalled possibly, but cannot be surpassed, by any method of internal urethrotomy.

I am, Sir, yours, &c.,

HENRY MORRIS.

Mansfield-street, Portland-place, W., Sept. 28th, 1880.

To the Editor of THE LANCET.

SIR,—In the correspondence in your columns relative to the comparative value of the splitting operation for stricture *versus* the internal cutting operation, it is to be noticed that the surgeons who are in favour of Mr. Holt's plan of treatment say very little or nothing of their experience with the urethrotome. In your last issue Mr. James Lane states that he has "never practised it." Mr. Heath is silent on this point, and Mr. Macnamara confines himself to a statement of a few difficult cases and a general praise of the operation.

These remarks in favour of Mr. Holt's operation have, no

doubt, been called forth by the ungenerous and unfair criticism of some gentlemen who, as Mr. Lane has shown, must know nothing either of the practice of the operation, its after-treatment, or effect.

The question is not, is Mr. Holt's operation a safe one or a serviceable one, but rather, is it the best treatment by operation? This cannot be decided by the statements of gentlemen who have only experience of the one or the other, but not of both.

Now, the splitting operation is one method, Mr. Holt's, and stands by itself. On the other hand, by the term urethrotomy many operations are included, some of them differing altogether from others, both in utility and method of procedure. I can well understand surgeons getting satisfied with Mr. Holt's operation and remaining there until time has proved one form of urethrotomy superior to all others.

I have seen Holt's dilator used in very many instances, both in this country and in Paris, where M. Dolbeau used it frequently; indeed, in 1872 I never saw him employ any other method. The only fault that can be found with this operation is that, as I have seen, a very obstinate discharge results, defying all treatment. I think this has also occurred in Mr. Lane's practice, and I recollect Mr. Juler telling me of a similar case or cases. One very bad case of stricture resulted from an attempt to forcibly dilate; but here the operation seems to have been badly performed and abandoned. My experience differs from that of Mr. Heath, inasmuch as I have found that strictures forcibly dilated and then neglected by the patient, as so many are, after they are divided, resist gradual dilatation with soft instruments far more than those operated on by internal urethrotomy; the former resembling a traumatic stricture; the latter, having a cicatrix or cicatricial splice in one place only, is much more amenable to treatment.

Such accidents as the instrument passing into a false passage, and then used, as related by Mr. Heath, causing two deaths, half of the whole number quoted, could not have occurred by the use of Mr. Teevan's urethrotome, unless the precautions enjoined by that surgeon be wilfully neglected.

I have seen various urethrotomes used, but none give such results as that devised by Mr. Teevan, while the risk is almost nil. Many and many times I have witnessed the operation by this instrument, and have also used it myself in some dozen cases; but I never saw any complication arise but once, and that was hæmorrhage, soon checked. In this case there was too great haste used, and too little precaution. However, the case did well, and twelve months afterwards he was passing a No. 20 French size. If this urethrotome be passed, and urine is seen to flow along it, it is quite impossible for any sacrifice of life to occur from cutting or splitting false passages. Without doubt, Mr. Holt's operation is of great value, and far superior to all the old, and the majority of the new, urethrotomies; but until the surgeon has had a full trial of Mr. Teevan's instrument he should not decide that Mr. Holt's operation is the best for the patient.

I am, Sir, your obedient servant,

HORACE MANDERS, F.R.C.S.,
Late House-surgeon, St. Mary's Hospital
and St. Peter's Hospital, &c.

Yorktown, Surrey, Sept. 29th, 1880.

TREATMENT OF HÆMOPHILIA.

To the Editor of THE LANCET.

SIR,—The interesting history of a fatal case of hæmophilia, under the care of Dr. Thorowgood, in the West London Hospital, related in your impression of Sept. 4th, has prompted me to give some particulars of a case of successful treatment in a severe attack of this distressing complaint I witnessed some years back; as the facts impressed themselves on my memory, I am the better able to dispense with the omission of notes taken at the time, which I unfortunately neglected. It was in a patient of Mr. Sloman's, of Farnham, whom I was assisting at the time.

A stout, healthy lady, between fifty and sixty years of age, was suddenly attacked in bed at night with profuse bleeding from the nose. I was sent for, and the patient, whose indomitable pluck and steady coolness under a full knowledge of the danger she was incurring, contributed

much to the fortunate issue, told me that a brother had died in a few days from uncontrollable bleeding following some very trivial skin wound, and that an aunt had frequently suffered from copious bleeding consequent on very inadequate exciting causes.

The patient was treated in the routine manner—astringents syringed into the nasal fossæ, ice, iron, and ammonia internally, and finally plugging the nares; but all to no purpose. The bleeding, if it ceased for a time, soon came on with redoubled energy; the patient at intervals vomited quantities of dark blood.

I was with the patient two nights, who, notwithstanding the increasing pallor, anæmia, and weakness, preserved her spirits wonderfully. After forty-eight hours of this continuous bleeding, it was evident that unless the hæmorrhage could be stayed death would speedily ensue, and as a last resource in a sort of empirical way we determined to try the effect of diminishing the blood-pressure by opening a vein in the arm. The state of the patient, while it nerved us to adopt any probable means of staying the flow, made recourse to this particular remedy without previous experience an anxious proceeding. Mr. Sloman opened a vein in the bend of the left arm with some difficulty, owing partly to its small size, and partly to the presence of much superficial fat. The nasal bleeding stopped as soon as a little dark blood had flowed away. After making sure that no further loss was taking place, the vein was closed. The hæmorrhage did not return, and from thence forward the patient made a protracted, but perfect, recovery.

In two other cases which I can call to mind—a gentleman of thirty and a girl of seventeen years, both with well-marked hæmorrhagic diathesis, and with hereditary history of the complaint—I have tried venesection, and in both cases success has been immediate and complete. Erichsen advises the application of continuous cold to the bleeding surface, if possible, combined with pressure, and mentions several cases where this plan has been successfully tried. Next to the constant loss the locality whence it comes is most important, and as it generally proceeds from sources difficult of application of mechanical pressure, in the majority of the cases one hears of, the remedies, internal and otherwise, used seem perfectly valueless, and the patients, if they recover, do so in spite of the means to help them. I have a family of which two members, females, are bleeders. In one of these patients a slight attack from nose and mouth passed off after twelve hours or so; but in the event of an attack lasting longer, or being very serious from the amount of loss or condition of the patient, if the bleeding surface was difficult to reach, I would open a vein at once, and would trust to this measure alone locally, but if compression could be used I would try this means first, with the addition of hot water, at a temperature of 50° or 60° C., to the bleeding surface, as has been found so useful in uterine hæmorrhage. May there not be a connexion between the hæmorrhagic diathesis and marsh miasm? In all the cases I have been able to investigate either the parents or the patients themselves have lived for some long time in an aguish district, or have had ague themselves. Perhaps some of your readers could throw light on the matter.

I am, Sir, yours very truly,

HENRY FINCH.

Colchester, Sept. 4th, 1880.

ENTERIC FEVER IN INDIA.

To the Editor of THE LANCET.

SIR,—All those who aim at precision in diagnosis must be thankful to Dr. Ranking (*vide* THE LANCET, July 31st) for his opposition to the idea that enteric fever in India is only a form of malarial fever. It is reasonable to suppose that a tropical climate may to a certain extent modify the course of the disease, but it cannot do away with its essential characteristics, either clinical or pathological. In India there may frequently be some difficulty in distinguishing between remittent malarial fever and enteric fever. There is difficulty in Europe in diagnosing some obscure tubercular cases from enteric fever. On this account, however, no physician in Europe classes enteric fever as a mere form of tuberculosis. A very great obstacle to the exact differentiation of enteric fever in India is the disregard of systematic and repeated temperature-taking. A person is said in a lax way to be suffering from "fever;" and if diaphoretics and quinine fail to restore the patient, opprobrious epithets such

as "malignant" are applied to the fever, and finally the thermometer is brought into very vigorous use. The course of the affection having been neglected in its beginning, routine thermometrical observations are taken when the time for diagnosing has long passed away and that for guessing has arrived.

Dr. Ranking goes on to say that natives suffer more from enteric fever than Europeans, or at least more than those Europeans who take proper sanitary precautions. As I do not know what Dr. Ranking's data are, I do not for a moment mean to dispute his statement, but as the subject is such an important one, I feel in duty bound to say that my experience does not make for a like conclusion. I have had considerable experience among the villagers in the Deccan; and as the medical arrangements in several of the Famine Relief Camps in the Maratha country were under my supervision, I had daily opportunities for observation. One camp, which may serve as a specimen of the rest, had on an average four thousand inmates. These people were of both sexes, all ages, and represented the usual castes met with in the Deccan, with the exception of Brahmans and Parsees. The adults suffered from extreme debility or actual disease. Many of the children were healthy orphans. There was a large staff of natives in good health, performing menial offices in the camp, and living under the same circumstances as the sick and feeble. The overcrowding was unavoidably very great; even in health the majority of the people would have been dirty in their habits, and when admitted for famine relief weakness and disease had made them too apathetic to attempt to observe the merest appearance of decency, far less cleanliness. The camp was in use for a year, and consequently the ground was thoroughly impregnated with organic matter. The drinking water was neither filtered nor boiled. No case of enteric fever was diagnosed during life. More than two hundred post-mortem examinations were made by myself on persons of both sexes and all ages. The first hundred bodies were selected as those of people who had died from gastro-enteric affections. The appearances of enteric fever were never found. On the contrary, an atrophy of Peyer's patches seemed to be a usual result of long privation. The people, in short, were placed in the most favourable circumstances for imbibing enteric poison, and yet the specific fever was wanting. Analogous observations were made on the absence of certain diseases that would probably have occurred in Europe under like circumstances. Ulcerative and gangrenous stomatitis were of frequent occurrence, in fact, almost endemic, but no case of diphtheria was observed. Though many autopsies were made of the bodies of persons who had died with sores of long standing, no case of amyloid kidney was seen. Most of the people had suffered for two or three years from want of proper food, clothing, and shelter, and yet phthisis was almost entirely absent. I do not wish to be understood to imply that enteric fever does not occur among natives. I merely wish to indicate that my experience tends to make me think that it is not frequent.

I should add that I have had many opportunities in Scotland of studying the disease both clinically and pathologically.

I am, Sir, yours, &c.,

E. D. MACKELLAR, M.B. Glasg.

Poona, Sept. 2nd, 1880.

EFFECTS OF THE INHALATION OF PURE NITROGEN GAS.

To the Editor of THE LANCET.

SIR,—On August 16th I was called by a coastguardsman to come at once to Mr. Fleuss, who had been walking under water at Fishbourne Creek, and had met with an accident. On arrival I found the patient in bed, wrapped in blankets; surface cold; temperature in axilla 96°; pulse 100, small and weak; heart sounds normal but weak; left lung normal; right lung slightly dull on percussion, and fine crepitation heard all over. I was shown a quantity of blood which he had spat up, and whilst I was in the room he spat up about an ounce of bright arterial blood; later, frothy and mixed with mucus. The conjunctiva of both eyes was intensely injected, and round about the eyes and lids purpuric, ecchymosed spots appeared. Was quite sensible and clear; no headache or nausea; no symptom of carbonic-acid poisoning.

History of the accident.—The apparatus with which Mr. Fleuss was experimenting on this occasion was not his patent diving-dress, but was a new invention for the purpose of entering smoke or mines. Mr. Fleuss proved by his having remained under water for nearly three-quarters of an hour that this dress could be equally adapted for going under water where protection from cold is not necessary. I have Mr. Fleuss's permission to describe the apparatus, which is patented. It consists of a cylinder containing oxygen under pressure, a bag into which the oxygen escapes, a purifier containing caustic soda to filter the expired air of its CO_2 , and a tight-fitting respirator or mask covering mouth, nose, and ears, with glass covers for the eyes. This mask is attached to the purifier by two valved pipes, one an expiring pipe and the other an inhaling pipe. The expired air passes through the filter, is robbed of its CO_2 , it then mixes in the bag with oxygen, and is ready to be reinhaled. Mr. Fleuss had been under water for some time, had walked across the bed of the river from one side to the other, and had turned to walk back again. He says he wished to try the experiment of using up all the oxygen in the bag before introducing a fresh supply, instead of allowing the flow of oxygen to be constant (as is the rule in using either this or the diving apparatus). Thinking he would have ample warning of the diminution of the oxygen, and of when it would become necessary to introduce a fresh supply, he turned off the oxygen at the cylinder. All this time the expired air was passing through the caustic soda. Having proceeded under water about half-way across the river, without warning and without any feeling of oppression, giddiness, nausea, or any other symptom, he suddenly lost consciousness, and not answering the signal communicated by the line, was immediately brought to the surface by his friends, who were accompanying him in a boat. What had occurred was as follows:—At the moment the oxygen was turned off the bag contained one-sixth of a cubic foot of the mixture of exhaled breath, with its complement of added oxygen. This mixture was rebreathed, and again passed through the filter until all the oxygen was used up, at which moment the next inhalation was one of pure nitrogen gas, with the effects described.

Mr. Fleuss informs me that in experimenting on himself he can tell in a moment if CO_2 has passed the filter; if this occurs he turns on more oxygen, which so far dilutes the poison as to cure the feeling of CO_2 inhalation, and gives ample time to get to the surface. It would seem that as long as any oxygen is present the excess of nitrogen is not felt, nor is any warning given of the need of a further supply; but the instant all the oxygen is used, or the proportion of oxygen falls below a certain point, the next inhalation causes such excessive arterial tension as to produce immediate loss of consciousness, and even rupture of loosely-supported capillaries. Dr. Richard Neale, in advocating in THE LANCET of Aug. 28th the purification of vitiated air in confined spaces by means of a "chemical lung," points out a modification and further application of Mr. Fleuss's patent, which is already in successful operation.

Your obedient servant,

Ryde, Isle of Wight, Sept. 1880. CHANNING NEILL, M.D.

CHIAN TURPENTINE.

To the Editor of THE LANCET.

SIR,—Having received the following account of Chian turpentine, and the probable supply of it this year, from Mons. D. Spadavo, French consul at Chio, I think it may prove interesting to the medical profession, and therefore send it to you for publication. I may add there is now some genuine Chian turpentine of this year's importation offered in the London market, for which a high price is asked:—

"I am happy to give you the information you require relating to Chian turpentine. This drug has not been collected in our island for many years, and I believe that the greatest quantities of Chian turpentine sold as such in England were mere falsifications, or another kind substituted for it. Chio may possess about a thousand turpentine trees, some exceedingly old—up to eight or nine hundred years, and varying from half a yard to ten or twelve yards in circumference. These trees when well cultivated may give from two to three kilogrammes of turpentine [a year?]

"The turpentine is collected by incisions made in the

trunk of the tree about April, and which are renewed every year.

"The fruit of this tree, when ripe, is collected and pressed in the same way as they do olives; it gives a magnificent oil, very much liked by the inhabitants, and often employed instead of butter. As soon as the fruit begins to get ripe the flow of the turpentine ceases; this happens about the middle of August.

"This year the inhabitants have been surprised to receive orders for the collection of turpentine, as it has been asked for in England and bought at the rate of six shillings the oke (or 1600 grammes). The island has not produced over 700 or 800 kilogrammes this year, as many have not been informed in time to incise the tree.

"Owing to its cheapness the possessors of these trees do not give themselves too much trouble in collecting it clear, and they let it flow on the sand, which is taken with it. We have not the means to get it cleared, and are obliged to send it as it is collected."

I am, Sir, yours, &c.,

New Cavendish-street, Sept. 28th, 1880. WM. MARTINDALE.

CONIUM IN CANCER.

To the Editor of THE LANCET.

SIR,—Permit me to draw the attention of yourself and readers to what is to me, at least, a new experience.

About a month ago I amputated at our infirmary a very large scirrhus breast in the first stage of ulceration. The extensive wound which was left open (as I have always done of late years) was dressed with a weak solution of carbolic acid on lint; this was continued for a week. The patient had many symptoms of uterine cancer, and had much vaginal discharge, with pain. At the end of a week, having procured a supply of fresh extract of conium, I put her under three doses a day of fifteen grains each. Within twenty-four hours of beginning the drug the nurse observed that the lint dressing on removal was of a bright-green colour—in fact, the colour of the mixture the patient was taking. Thinking it might be connected with the carbolic-acid dressing, we discontinued it, and dressed the wound with lint and water only. The dressings came away coloured as before, and have continued so up to the present. The wound is closing very rapidly, the colour of lint now partaking of a yellow or apple green. During the first few days a piece of lint moistened with the mixture, and compared with the lint removed from the wound, was scarcely distinguishable from the latter, except by the pus. The secretions are unaffected in colour or in any way. I may add that the vaginal discharge has ceased, and the uterine pain and symptoms have all but disappeared. Be this the result of the full doses of conium or not, I feel inclined to give this drug a full and fair trial in all cases which may in future come under my care, in both internal and external disease, in full doses; procuring, of course, fresh extract.—I am, Sir, yours faithfully,

Chelmsford, Sept. 20th, 1880. JAMES NICHOLLS, F.R.C.S.

* * As may be ascertained on reference to Pereira's *Materia Medica*, the use of conium, as a reputed remedy for tumours and cancers, is as old as anything in therapeutics. Pliny says "it reduces all tumours." Avicenna extolled its use for tumours of the breast and testicle. Storck and others recommended it for cancer as far back as 1762. Bayle recorded forty-six cases of cancerous disease cured, and twenty-eight ameliorated by hemlock. There is, therefore, no novelty in the treatment, but many years ago it was common, but unhappily unsuccessful.—ED. L.

THE SERVICES.

WAR OFFICE.—Surgeon W. Maunsell Collins, M.D., from the Scots Guards, to be Surgeon in the Royal Horse Guards, vice H. F. L. Melladew, M.D., promoted; Brigade-Surgeon Joseph Coleman Hornsby Wright, M.D., has been granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major Channey Graves Irwin, M.B., from half-pay, to be Surgeon-Major.

ADMIRALTY.—The following appointments have been made:—Fleet Surgeon Michael W. Cowan to the Royal Marine Division at Portsmouth; Staff Surgeon Charles L. Ridout to

the *Tourmaline*; Staff Surgeon Septimus Lexton to the *Duncan*, for temporary service. Fleet Surgeon J. Caldwell to the *Nankin*; Staff Surgeon A. B. Trousdell to the *Duke of Wellington*, for Portsmouth Dockyard; Surgeon A. T. Corrie to the *Flora*; Surgeon W. Thompson to the *Rambler*. Staff Surgeon Henry Hadlow has been promoted to be Fleet Surgeon, with seniority of the 20th ult.

PARIS.

(From our own Correspondent.)

ALTHOUGH the medical journals have not yet taken cognisance, as the lawyers say, of the smells of Paris, the agitation which has been carried on for the last two months in the lay press has already borne useful fruit. The real cause of the nuisance is now known to reside in the *depotoirs* surrounding Paris, and especially in one of these establishments, for transforming the metropolitan nightsoil into chemicals, which is situated in the plain of St. Denis. A writer in the *France*, M. Charles Laurent, speaks of it as follows:—"Everything agrees in pointing out a well-known factory in the plain of St. Denis as the sole origin of the bad smells which infect Paris. This factory collects all that is unearthly from the city, in order to extract chemicals and fat. It diffuses in the neighbourhood such a strong smell of rotten cabbage that even in the coldest weather 'young ladies' (*sic*) who have recently crossed the Channel are seized again with a kind of sea-sickness."

Now that public attention has been forcibly called to the insanitary condition of the town generally, it would be well if some influential organ would protest against the disgraceful condition of several of the Paris hospitals. The Hôpital Laennec, for instance, is very little better than a slaughter-house for incurables. The wards situated upon the ground floor are especially badly kept. Odours which emanate from the closets impregnate the atmosphere, and culminate in an almost insupportable stink. Close to the small dungeon which is used as a speculum-room, a few days since I noticed with surprise on the clothes of a woman some lively specimens of the *Cimex lectularius*, and on expressing my astonishment to one of the pupils, he informed me that the insect has its habitat at Laennec. He furthermore volunteered the statement, which is probably strictly true, that a few months' residence at that institution is sufficient to tuberculise the strongest inmate.

M. Jules Guérin, who, in his public capacity, may be summed up as a scientific obstructionist, does not set a very high value upon M. Pasteur's experiments; and he does not hesitate, moreover, to proclaim his scepticism. At a recent meeting of the Academy of Medicine he promised to show that what is true in the recent communication of M. Bouley is a matter of common knowledge (*court les rues*), and that what is new is absolutely false. If M. Jules Guérin's adverse opinion were not almost sufficient in itself to stamp M. Bouley's discoveries with interest, it might be observed that the epigram he has applied to them is as old as the judgment is unjustifiable.

Those who are passing through Paris at the present moment will do well to visit the Hôpital Laennec. There is now a case of generalised scleroderma, under the care of M. Legroux, which will well repay the trouble.

Obituary.

THE HONOURABLE JOHN IMRAY, M.D.

WE much regret to have to record the death of this distinguished West India practitioner, which occurred in the island of Dominica, on Sunday, the 22nd August last, of dysentery.

Dr. Imray, who was closely connected with Dr. Porteus, one of the most celebrated Bishops of London, was born in the north of Scotland on January 11th, 1811; and he received his medical education in Edinburgh, where, in 1831, he obtained the diploma of the College of Surgeons. He soon afterwards settled in Dominica, in which island his

elder brother, Dr. Keith Imray, who was well known in the profession in those days, was then practising. By skill and hard work Dr. Imray soon became the leading physician in Dominica, and he retained this honourable position until a few years ago, when he retired from the active exercise of his profession.

In 1838 he published in the *Edinburgh Medical Journal* an article on Epidemic Yellow Fever, and three years afterwards contributed to the same periodical a long paper entitled, "On the Nature, Causes, and Treatment of Yellow Fever." These articles deservedly attracted considerable attention, and his clear and accurate description of a disease which was then but little understood caused him to be considered an authority on the subject. He was, in fact, the first English practitioner who drew attention to certain important pathological characteristics of this fatal disease, and the learned Dr. Copland frequently quoted him in the article on Yellow Fever in the celebrated "Dictionary of Medicine." It may here be mentioned, as an important fact in the present day, that Dr. Imray's views in regard to the non-contagiousness of yellow fever underwent an entire change, for of late years he was impressed with the idea that the disease occasionally, if not always, manifested contagious properties.

In 1848 he published in the *Edinburgh Medical Journal* an able article on the "Characters of Endemic Fever in the island of Dominica," and subsequently he published several articles in the pages of this journal, his last being on the "Treatment of Tetanus by Opium and Hydrate of Chloral in Combination." In addition to writing these valuable papers, he was the author of the "Memoir on Yaws," published, in 1873, in Dr. Gavin Milroy's "Report on Leprosy and Yaws in the West Indies." This "Memoir," which gives evidence of much learning and deep reading, gained for Dr. Imray the distinction of being held to be the first living authority on frambesia.

When it is remembered that a medical man, practising in a small island in the tropics, was able to make for himself a reputation as an authority on several diseases, he must be considered to be a man of more than ordinary intellect; but when, in addition to this, such a man is able to carve out for himself a name as an able botanist, to leave his mark as a successful politician, and to be famed throughout the tropical world as the most enterprising and successful agriculturist in the West Indies, he must be held to be remarkable; and, indeed, Dr. Imray was a remarkable man, and one that the profession has need to be proud of.

For nearly half a century he was the friend and correspondent of Sir William Hooker, and his son, the present director of the Royal Gardens at Kew; and many plants have been named in his honour by Lindley, by the Hookers—father and son, and by other botanists. He was also a well-known and able contributor to the pages of the *Gardeners' Chronicle*, the *Technologist*, the *Journal of Applied Science*, and *Nature*.

At the time of the International Exhibition of 1862 his efforts, as chairman of the Dominica Committee, caused the island's show to eclipse far richer colonies; and to him the jurors awarded two medals, one for special services, and the other for his valuable collection of the native woods.

His introduction into Dominica of the cultivation of limes and of the Liberian coffee, whilst enriching himself, helped to bring forward once more the ancient prosperity of the island; and it is already proposed by an admiring public to erect some permanent memorial to one who has proved such a benefactor to the colony.

In the politics of the country Dr. Imray until lately took a prominent part, and as a leading member of the Executive Council, he was the trusted and honoured adviser of all the Governors. As chairman of the Board of Health he, on several occasions, prevented the introduction of contagious diseases from the neighbouring colonies; and the establishment of the Roscar Infirmary, of which institution he was the medical officer for over thirty years, was mainly due to his exertions and monetary aid.

In private as well as in public life he was the type of the English gentleman. Upright and honourable in all his dealings, his word once passed was his bond; and never from the time of his landing in the island to the day of his death was he known to have committed a wrong act. Always of a religious disposition, he was a prominent member of the Anglican Church, and at its disestablishment in the island he subscribed very largely for its maintenance.

His private charities were innumerable, though for the

most part secret, and as a necessary consequence his death was bewailed by the poor throughout the length and breadth of the island.

To his immediate friends—he was unmarried and without relatives in Dominica—his death came as a terrible blow; for his kindly disposition, his flowing wit, and his highly cultivated mind, had raised up in those who had the privilege of his friendship an affection the depth of which was unknown until the good old doctor was no more.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Sept. 23rd:—

Fowler, Charles Henry, East Kirkby, Lincolnshire.
Hakim, Pherzeshá M., Bombay.
Mody, Nanabhooy C., Bombay.
Perkins, George C. Steele, Exeter.
Wallace, Robert Smith, Arnold, Notts.

The following gentleman also on the same day passed his Primary Professional Examination:—

Cockell, Edward Seaton, Guy's Hospital.

THE Hospital Sunday collections at Yeovil on the 26th ult. amounted to about £105.

THE Convalescent Hospital for the county of Hertford, at St. Leonards-on-Sea, will be opened by the Princess Christian on October 21st.

At the annual meeting of the Royal Albert Asylum for Idiots and Imbeciles held at Newcastle on Wednesday, Mr. Joseph Cowen, M.P., said that he had ascertained in connexion with an inquiry in which he had been associated, that there was collected in London alone, by voluntary subscriptions, for charitable purposes, nearly £6,000,000 a year. If to this sum were added the amount paid as poor-rates, there would result a total of something like £8,000,000 contributed in the metropolis annually towards the relief of suffering, distress, and poverty.

SUPERANNUATION.—The following Poor-law Medical Officers have received superannuation allowances:—Mr. Arthur J. Nunn, late of the Alderbury Union, £20 per annum; Mr. A. G. Roper, late of the Croydon Union, £100 per annum.

MEDICAL MAGISTRATES.—Dr. Edward Davies, of Wrexham, has been nominated by the Lord Lieutenant as a Magistrate for the county of Denbigh. Dr. Walker, of Brierley Hill, has been placed on the Commission of the Peace for the county of Stafford.

BEQUESTS.—The West Norfolk and Lynn Hospital has received a legacy of £100 from the late Daniel Gurney, Esq., of North Runcton, Lynn. By the will of Mr. Francis Adams, late of Bristol, £250 is bequeathed to the General Hospital and to the Royal Infirmary of that city.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

BLAKE, J. F., L.R.C.P.Ed., L.F.P.S.G., has been appointed Medical Referee on Sanitary Subjects to St. Margaret's and St. John's Ratepayers' Protection Association.
BULLOCK, H., F.R.C.S.E., L.S.A.L., has been reappointed Medical Officer for the Cranford District of the Staines Union.
CALLCOTT, J. T., M.B., has been appointed Deputy Medical Superintendent of the Durham County Asylum.
CLAPP, R., L.R.C.P.L., M.R.C.S.E., has been appointed Assistant Medical Officer to the Barnwood House Hospital for the Insane, vice Warren, resigned.
CREERY, J., M.B., has been appointed House-Surgeon to the Derry County Infirmary.
D'ALTON, P. R., L.R.C.S.I., has been appointed Medical Officer to the Oranmore Dispensary, Galway Union.
EDWARDS, D., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Llanbryn-mair District of the Machynlleth Union.
ERSON, E. G. L., L.R.C.P.Ed., has been appointed Medical Officer for the Lindley-cum-Quarmby District of the Huddersfield Union, vice Ellerton, resigned.
FERGUSON, H. L., L.R.C.S.I., has been appointed Assistant-Surgeon to the National Eye and Ear Infirmary, Dublin.
GAFFNEY, T., L.R.C.P.Ed., L.R.C.S.I., has been appointed Medical Officer to the Keadne District of the Boyle Union.

HANDS, A., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the Wednesfield District of the Wolverhampton Union, vice Broom.

HARDY, J. G., L.R.C.P., has been appointed Junior Assistant Medical Officer to the Durham County Asylum.

KIRSOPP, T., M.B., M.R.C.S.E., L.S.A.L., has been appointed Resident Medical Officer to the York Dispensary, vice Spencer, resigned.

LAYCOCK, G. L., M.B., has been appointed additional Assistant-Physician to the West-end Hospital for Diseases of the Nervous System.

LINE, W. H., M.B., has been appointed Demonstrator of Anatomy at Carmichael College.

MACNAMARA, R., jun., L.K.Q.C.P.I., L.M.R.C.S.I., Anatomical Demonstrator Royal College of Surgeons, Ireland, late House-Surgeon Alnwick Infirmary, and Surgeon 2nd Northumberland Artillery Volunteers, has been appointed Supernumerary Colonial Government Surgeon to the Island of Trinidad, West Indies.

PRIDEAUX, T. E. P., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the First and Second Districts and the Work-house of the Wellington Union, vice Kidgell, resigned.

PRINGLE, J., M.R.C.S.E., has been appointed Medical Officer for the Holme District of the Howden Union.

RUTHERFORD, R. L., L.K.Q.C.P.I., has been appointed Senior Assistant Medical Officer to the Durham County Asylum.

SMITH, T. O., M.B., B.Ch., has been appointed Medical Officer to the Kinnetty District of the Parsonstown Union, vice Dudley.

SWINSON, G. N., M.R.C.S.E., L.R.C.P.Ed., has been appointed Medical Officer to the Third District of the Royston Union.

TICHEURST, C. S., M.R.C.P.Ed. &c., has been appointed Medical Officer of Health to the Petersfield Rural District for three years, at a salary of £73 10s. per annum, vice T. Moore, F.R.C.S.E., resigned. Also Medical Officer and Public Vaccinator for No. 2 District of the Petersfield Union, and Surgeon to the Petersfield Union Infirmary, vice T. Moore, resigned.

Births, Marriages, and Deaths.

BIRTHS.

BARK.—On the 20th ult., at Aston-road, Birmingham, the wife of Ernest Bark, L.R.C.P.L., of a daughter.

CONSTANT.—On the 14th ult., at Ferndale-park, Tunbridge Wells, the wife of Surgeon-Major F. G. Constant, M.D., 12th Bengal Cavalry, of a son.

FLOYD.—On the 14th ult., at Rectory-place, Woolwich, the wife of John Floyd, M.R.C.S.E., of a daughter.

HARRIS.—On the 24th ult., at Cold Harbour-lane, S.E., the wife of Henry Harris, M.R.C.S.E., of a daughter.

MCAUGHTAN.—On the 29th ult., the wife of Thos. McNaughtan, M.D., of Blackpool, of a daughter.

NAPIER.—On the 28th ult., at 3, Royal-terrace, Crosshill, Glasgow, the wife of Dr. A. Napier, of a son.

THURSTAN.—On the 23rd ult., at The Hollies, Windmill-road, Croydon, the wife of Paget Thurstan, B.A., M.B., of Lombard-street, E.C., of a son.

WEATHERLY.—On the 20th ult., at Portishead, Somerset, the wife of Lionel A. Weatherly, M.D., of a daughter.

WILSON.—On the 22nd ult., at 7, Pleasant-row, Newcastle-on-Tyne, the wife of Adam Wilson, F.R.C.S.Ed., of a son.

MARRIAGES.

ADAMS—WROTH.—On the 23rd ult., at the Parish Church, Begbury, Devon, by the Rector, the Rev. F. Farrer, John Adams, L.R.C.P.L., of Aldersgate-street, E.C., to Ellen Sparrow, eldest daughter of John Wroth, Esq., of Coombe, Begbury, Devon.

BARKER—DELMEGE.—On the 9th ult., at St. Peter's Church, Dublin, Arthur Edward Barker, Esq., F.R.C.S.E., of Harley-street, London, to Emilie Blanche, youngest daughter of Julius Delmege, of Fitz-William-square, Dublin.

BEAUMONT—CLARKE.—On the 25th ult., at St. Saviour's Church, Walthamstow, Essex, Charles G. Beaumont, Esq., M.D., of Shirley, Hants, to Lucie, eldest surviving daughter of the late Seymour Clarke, Esq., of Northcotts, Walthamstow.

BETTS—FITZGERALD.—On the 25th ult., at the Friends' Meeting House, St. Martin's-lane, Westminster, Edward George Betts, M.R.C.S.E., son of John Betts, of Holloway, to Charlotte Mary, eldest daughter of Alexander Fitzgerald, of Millbank-street, Westminster.

HAMILTON—RINGWOOD.—On the 28th ult., at Christ Church, Leeson-park, by the Rev. Henry J. Ringwood, B.A., Curate of Fullamore (brother of the bride), assisted by the Rev. James Hamilton, B.A., Rector of Pomeroy, co. Tyrone (brother of the bridegroom), and the Rev. William Turbill, Rector of Drumree, Portadown, Archibald Alexander Hamilton, M.B., B.Ch. Univ. Dub., youngest son of the late Thomas Hamilton, Esq., of Grange, Moy, co. Tyrone, to Annie Elizabeth, eldest daughter of the late Rev. H. T. Ringwood, M.A., of Wilson's Hospital, Westmeath.

KEYWORTH—GWYNN.—On the 25th ult., at St. Peter's, Regent-square, George Hawson Keyworth, M.B., of Wem, Shropshire, to Gertrude Mary, only daughter of the late Rev. Thomas Gwynn, M.A., of Great Marlow, Bucks.

DEATHS.

CLEMENT.—On the 20th ult., at his residence, Woodville, Watford, Herts, Augustus Ward Clement, M.R.C.P.L.

HUTCHINSON.—On the 19th ult., at Scarborough, Richard Scholes Hutchinson, M.D., late of Nottingham, aged 77.

TAYLOR.—On the 18th ult., at Naini Tal, India (killed by a landslide), Leonard Taylor, C.S. Assistant Commissioner, fourth son of David Taylor, M.R.C.S.E., of Kennington-park-road, S.E., aged 27.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

A STRANGE SUGGESTION.

A DUBLIN newspaper, in recommending the Catholic University Medical School to the favour of medical students, says that it should be given the preference by Roman Catholic parents, not only on account of the security they must feel in having their children conducted through the mysteries of that dangerous study by Roman Catholic masters, but also in consideration of the vast patronage of the Roman Catholic hierarchy and priesthood in the matter of medical appointments in almost every part of Ireland. We are aware that the majority of Poor-law medical appointments in Ireland are decided by the religion of the candidate, and not by the professional merit he may possess. We regret the fact, and deplore also that any journal should strive to induce students of medicine to join an institution by advocating its claims on such questionable grounds. The *Dublin Evening Mail*, in referring to this matter, recommends competitive examinations as the only remedy to prevent the disgraceful touting and the sectarian hugger-mugger which attend the bestowal of Poor-law medical appointments in Ireland. This proposal is worthy of consideration, but at the same time the natural pociivities of the Irish people cannot be altogether ignored.

COATED PILLS.

To the Editor of THE LANCET.

SIR,—For several years I have been in the habit of using coated pills for all general purposes, both in private and very extensive colliery practice, without finding them to differ at all in their action from pills prepared from similar formulæ in my own surgery. Doubtless there are films and films; but if the particular film with which a pill is coated be inert and sufficiently soluble, I think I may venture to say that it is a harmless and elegant innovation, and that nothing but advantage is likely to result from its adoption. Moreover, in many instances I have found that a coated pill recommends itself to those patients one meets with who say, "Oh, I cannot take pills." I have a patient at present under treatment who would shudder at the sight of an ordinary pill, and vomit before it could pass the fauces; but who, when pills are coated, will freely swallow two at once.

Yours truly,

Sept. 27th, 1880.

O. U. I.

To the Editor of THE LANCET.

SIR,—My experience (an extensive one) of the use of coated pills has been entirely in their favour. Practitioners, patients, and assistants all praise the "sugar-coated pills." My medical friends speak with equal commendation of those supplied by good firms. The early education of general practitioners is now so altered that I fear some of us do not know good drugs and careful dispensing from their counterfeits. I shall be very happy to give Dr. Milne a list of the formulæ I have found so useful.

Yours truly,

Great Charlotte-street, S.E., Sept. 1880.

HENRY WILLSON.

DOCTORS AND DEATH CERTIFICATES.

MR. E. A. CARTAR, coroner, at an inquest held lately in Deptford, was told by the mother of the deceased child that it had been attended by an assistant for convulsions. On applying to the principal for a certificate of death, he said it would cost her 3s. 6d. She said, "Am I to understand that unless I pay 3s. 6d. you will call in the coroner?" He replied, "Certainly." There are some statements which are so incredible that the best way is simply not to believe them, and this is one of them. But it seemed to be credited by the jury. For our part we withhold credence from it till it is admitted or explained by the doctor implicated.

Double Qualification will find most of the information he is in search of in Hardwicke's "Medical Education and Practice."

Mr. Robinson should address his inquiry to the gentleman named.

"LEGALISED QUACKERY AND LOW CHARGES": ANOTHER DEFENCE.

To the Editor of THE LANCET.

SIR,—The letter of your correspondent, L.R.C.P., in yesterday's issue, deserves a more prominent place in your journal. Since we cheap dispensary doctors are accused by your leader writers of (to speak plainly) deliberately defrauding our patients, the type in which a refutation is printed should, on the "Audi alteram partem" system, be at least equally large, and the position in the journal somewhat prominent. I also want to add my testimony, based on two years' exclusive experience, to that of my colleague, "L.R.C.P."

Firstly, I want to point out that there is a possibility of acting honestly to patients, and still to have low charges. I assert that the average price of the drugs in a six-ounce mixture does not exceed 12., even if such drugs as quinine and iodide of potass, morphia, &c., are used. Let any medical man turn to his day-book, and by the aid of the price list of a good druggist compare the money value of 100 consecutive bottles of medicine. I do not believe it would come to more than 8s. 4d.

Again, let any gentleman really interested in this question go to the out-patient department of a general hospital. Let him there take the letters of fifty medical patients and of fifty surgical patients, and let him cast up the money value of the prescription, and it will not exceed 3d. per pint (or a week's supply). I exclude cod-liver oil, which costs a little over 1s. 2d. per ounce.

Again, let any gentleman take the published numbers of patients attending at a public dispensary, let him also take the published accounts of money spent on drugs, and he will find that it does not exceed 3d. per head per week. It is, therefore, evident that if you charge even so low as 1s. per week, there is a gross profit of 9d.

My own experience is that at a dispensary where the gross receipts during the quarter for January 1st till March 31st of this year exceeded £400, the drug bill was a little over £60, a sum coinciding remarkably with the figures quoted by my colleague "L.R.C.P."

It being now demonstrated that the thing can be honestly done, the question is, How is it that these private dispensaries are often disreputably conducted?

The greatest difficulty is to find able men, willing to work, and honest enough to do what is right by the patient at the outset, even in the early days, before the business pays. Moreover, everyone could not do it. What is required is experience similar to a hospital physician's, business capacity of no mean order, punctuality, and a little capital to bring it out, and, above all, you must be fond of the work, which is to all intents and purposes that of a physician at a hospital. For, indeed, when the attendance is numerous (at my place of business, I have reason to believe that I see on some days over two hundred people), you get the out-patients' department of the hospital repeated on a small scale, with this important difference, that the medical man is adequately paid for his work. I cannot help thinking that he also takes a greater interest in the individual cases, as each case has a direct money interest for him.

There are many other questions involved. I will, however, not trespass upon your space any more, except in this respect—namely, the question of ethics involved, and I maintain that "what a medical practitioner charges can never be a question of etiquette provided he deals honestly with his patients."

Yours obediently,

Sept. 26th, 1880.

M.D. Lond.

Ichabod.—Our correspondent will see that we have gone fully into the question of the grievances of the I.M.D. It appears unnecessary under the circumstances to publish the letter with which he has favoured us. *Provident Dispensary* is quite right. The confusion referred to is an inadvertence.

Mr. J. F. Nicholls.—See reply on page 404.

CHESTER WORKHOUSE.

To the Editor of THE LANCET.

SIR,—The attention of the guardians of this union having been called to a paragraph appearing in your publication of the 4th inst., containing certain statements as to the condition of their new workhouse buildings and the drainage, they direct me to inform you that the said statements are utterly untrue. I am, Sir, your obedient servant,

WM. KEARTLAND,

Chester Union, Chester, Sept. 21st, 1880.

Clerk to the Guardians.

PROFESSOR GOLDWIN SMITH ON DOCTORS.

WE cull the following from the *San Francisco Western Lancet*:—"At the annual dinner of Trinity Medical School, Toronto, Mr. Goldwin Smith, responding to a toast, spoke of the singular fact that quacks obtain much sympathy from the masses, who regard them as persecuted men of genius. He also said that there was no body of men—and he made no exception—to whom the world owed greater gratitude than it did to physicians. There was no body of men from whom society received so much, and to whom it paid so little. He thought a man setting out in the medical profession must have almost the spirit of a missionary. He must set out for the purpose of doing good, and not for reward. He was the slave who always worked. The lawyer had his vacation. Even the clergyman might leave his little flock for a time in the wilderness and take his holidays. But the medical man had no moment to call his own. He was at the common call at all hours, and he had often to deal with humanity in its most repellant states. But still he reaped a rich reward in doing boundless good, and had the regard of the sick man as his best friend in the very best sense."

G. G. J.'s knowledge of the individual in question appears to be equal to our own. Every registered practitioner is entitled to recover fees, according to his qualification or qualifications.

Mr. Joseph Schleman.—Any of the more sheltered southern suburbs.

CHANGE AS A MENTAL RESTORATIVE.

To the Editor of THE LANCET.

SIR,—I have been reading some articles on this subject by Dr. Granville, and feel inclined to make a suggestion, which may have occurred to some of those who read Dr. Granville's interesting papers.

I quite agree with Dr. Granville that, valuable as change is to many invalids and overworked persons, it is worse than useless for a doctor to tell a patient vaguely that he "requires a change." A month or two at the seaside, or on the Continent, or in a sea voyage, or in India, a run up to the hills, may be the change indicated; but in many cases it requires to be supplemented by a change of occupation, and not by thorough idleness. Most patients can best find out what that change should be, and need not be advised by the medical attendant; others will consult the doctor, or at any rate will thankfully receive any suggestions that he may have to offer.

Dr. Granville's suggestion is a shrewd one, that the family physician should consider what subjects have been especially taken up by other members of the family, past and present, in order to make use of any hereditary tendencies which might be of some practical service. It struck me that there is one subject which must be of immense interest to all patients if properly introduced to their notice, and that is religion. I do not mean that the doctor should become the spiritual adviser of his patient, or "preach" to him. If he does so, he will in most cases disgust his patient, and lose all influence over him. I mean that a doctor might in many cases in which he meets with a patient whose brain has been overworked with business and anxieties connected with the world we live in, or a patient whose brain has lost all its tone, so to speak, by having devoted itself exclusively to amusement until he has not an object of interest left in the world,—in a number of such cases, I say, that a doctor may find sufficient stimulus to the brain in questions which concern another world and another existence. The subject of religious thought is nowadays by no means a narrow one, and must possess considerable interest to everyone who has time to devote to it, and the number of books on the subject well worthy of attention, and written from every stand-point, are very numerous. The class of people to whom one could recommend such study, I fancy, might be easily induced to take it up. The overworked man of business, whose health seems to have been hopelessly lost by his efforts to do his duty, must feel disappointment in this world; but he may be induced to hope that a future world exists, and may be more satisfactory to his nature. The wealthy young man, who at last discovers that amusement when indulged in to excess ceases to please, or even causes disgust, is often unable to turn his attention to more serious pursuits. There is not enough stimulus; he does not need to gain a livelihood; he cannot hope to succeed, or some such reason occurs to him, and prevents him from even making an attempt. But there is something so new in the idea of another world and another existence, which might tempt him to read books, weigh arguments, and an interest might be created which would act as a stimulus to the brain, and at last bring back an interest in the life which he had considered worse than lost to him. In order to accomplish this, the doctor, whom I am supposing to be in the place of adviser, must use great tact, and be extremely careful to make the patient understand that he is inviting his interest to an attractive study, and not preaching him a sermon. He should have the names of a few good books to recommend as a beginning, and should be ready to suggest the name of some one who would be willing to assist him. This person could most naturally be a clergyman, who should be prepared to help in the same spirit as the doctor began. I would suggest that in most cases it would be better not to advise the study of Christianity in the first instance. Such people as I have described have very often anything but pleasing remembrances of early Christian teaching, and too often Christian theology is of a gloomy and repelling kind. Let our patient take a wider view of the subject first, and turn his attention to non-Christian systems. Four very interesting little works have been written

on non-Christian systems; those on Mahomedanism and Buddhism are especially interesting. Other larger works may easily be found. These books cannot fail to interest, and may arouse a desire to know more about Christian theology and Christian philosophy than can be obtained from reading ordinary religious works. Books on Church History and writings of rationalistic authors, with the answers given by the best of the orthodox school, are examples of what might be found of an interesting nature. Once prevail on such a patient, however hopeless his case might be before, to believe that another existence is in store for us after this life, and that it will be of a much happier and very different kind to this imperfect existence we are living now, and I believe we should have a stimulus capable of arousing his interest. Then, and only then, will sea-air, change of scenery and people, and perfect quiet be of the service we want. They will assist us when once we can make our patient to see that life is worth living, and we may find the strange but satisfactory result that the hope of another world has changed the present life from a misery into a pleasure; for health of the mind will often produce health of the body when all other treatment has failed.

Yours truly,

E. DOWNES, L.R.C.P. Lond.,
Medical Missionary of Kashmir.

August, 1880.

Gratis.—We cannot recommend such a course as our correspondent advises, but would earnestly dissuade him from it. Where would the profession land if every practitioner announced in a handbill his specialty, and proclaimed what he thinks his superior knowledge? We would urge "*Gratis*" to believe that if he only learns to labour and to wait, his good knowledge will be found out both by the public and by his professional brethren, when a pleasure and a respect will accrue to him which are not to be had by advertising.

Mrs. C. L. Murray.—The wife of a medical man, who is disabled by sickness, should apply to the Secretary of the Royal Medical Benevolent Fund.

A Constant Subscriber.—It is the rule generally followed.

EFFECTS OF AN EXCLUSIVE MEAT DIET.

To the Editor of THE LANCET.

SIR,—In answer to the query of "*Dietetic*," I may point out the fact that the diet of the ganchos of South America consists almost exclusively of meat, and of a kind not containing much fat; they eat occasionally a little maize or roasted mandioc (Cassava manihot); but for weeks together they live entirely upon meat, and certainly enjoy excellent health. I do not remember having seen any trace of scurvy amongst them. But I can give a case more to the point in my personal experience. While I was a prisoner in Paraguay, during the Brazilio-Paraguayan war, my captors gave me literally no other food during two months than meat (about half a pound to a pound per diem) and water, and for the next month a similar diet, but with less meat, and about thrice a week a very thin cake, certainly not weighing more than an ounce, of cassava meal. I suffered much from thirst, for very little water was given to the prisoners, but still more from a craving for vegetable food. Nevertheless, my health was excellent the whole of the time. I became, of course, as lean as a starved greyhound; but when I was rescued by the expedition sent by the Government of the United States for that purpose—under the fortunate mistake that I was a subject of the Republic—I was really as well as I had ever been during a singularly healthy life.

As to the effects of beef-tea and Liebig's extract, it is much to be regretted that they are still regarded by the public and by a few amongst ourselves as food instead of stimulants; and I would suggest that their injurious effects when used in the former capacity are due to the fact that their main constituents are the debris of worn-out cells, kreatine, inosine, kreatinine, and urea—excretive matters that the blood would normally have got rid of, and that beef-tea, except in the absence of uric acid, differs but little from healthy urine. I published some years ago a paper in THE LANCET, giving analytical proof of this.

Yours truly,

Stourport, Sept. 27th, 1880.

G. F. MASTERMAN.

A. S. G.—As Malta belongs to Great Britain, British qualifications confer the right of practice. But, in other cases, in order to practise there, it is necessary to pass the Medical Board of the Island. Even graduates of Malta have to do this. According to Hardwicke, in his work entitled "*Medical Education and Practice*," there is an excellent opening in Malta for one or two well qualified British practitioners. The prevalent diseases there include an endemic remittent fever common in the Mediterranean islands.

Mr. Henry Love.—Application should be made to the Registrar of the University and the Secretary of the College.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In your article in last Saturday's LANCET on the Cork Fever Hospital Inquiry, it is stated that Dr. Macnaughton Jones "was supported in his argument upon the nature and uses of pilocarpin by Dr. Gavin Duffy, of Dublin,"—a misprint, which I would ask you kindly to correct, for the name of,

Your obedient servant,

GEORGE F. DUFFEY, M.D.
Fitzwilliam-place, Dublin, Sept. 28th, 1880.

MEDICAL ADVERTISERS ABROAD AND AT HOME.

THE Secretary of the Board of Examiners of the Medical Society of the State of California has been directed to notify certain medical gentlemen in San Francisco—licentiates of the Board—that their advertisements in the Sunday papers, their handbills, and local signs, are unprofessional according to the code of ethics and the medical law, and that the Board requests them to withdraw the same. We get many things from America; would that it were possible to import an energetic Board to stop medical advertising amongst us!

Astonished.—The habit is a bad one; but it is to be rectified by remonstrance and friendly discussion.

A QUESTION OF TREATMENT.

To the Editor of THE LANCET.

SIR,—I am anxious to get some hints for the successful treatment of the following case. Will you kindly afford space to my letter?

The patient, a fairly healthy-looking man, of about twenty-six, is suffering, and has suffered for the last ten years, from a copious eruption of acne pustulosa on the chin and lower part of the cheeks. This eruption is accompanied by spots and patches of soreness upon the mucous membrane of the side of the tongue and lips. These spots are whitish in colour and semi-transparent. Excessive soreness is a marked feature of the spots upon the mucous membrane. The sides of the tongue present some thickening and slight furrowing, but not to any great extent. The patient's general health is very good, the only motive that induced him to apply to me being his anxiety to get rid of the local inconvenience. For various reasons I must exclude syphilis as the *fons et origo mali*. For some weeks I have administered the following with marked benefit: Iron and citrate of ammonia, one drachm and a half; iodide of potassium, one drachm; tincture of calumba, one ounce; chlorate of potash, two drachms and a half; glycerine, one ounce; water to eight ounces; one ounce to be taken three times a day. Much to my annoyance, on administering the above without the chlorate of potash, the spots and soreness of the tongue have returned with their former intensity, although the skin eruption continues to improve under the altered medicine. Can any of your correspondents give me any suggestions as to the local and general treatment of the case in reference to the tongue? Such is the soreness of the organ caused by this eruption that the patient is seriously inconvenienced both in speaking and eating. For local application I have used the glycerinum boracis of the Pharmacopœia, but without much benefit. The patient has some chronic soreness and redness of the edges of the eyelids, but no marked indications of the strumous diathesis. Any suggestions in reference to the treatment of the case will be highly valued. Perhaps some of your readers will be good enough to state their experience in cases of a similar description.

I am, Sir, yours faithfully,

September, 1880.

J. B. C.

A SELF-SUPPORTING DISPENSARY AT LEWISHAM.

WE are obliged for a copy of the Rules of a Self-supporting Dispensary at Lewisham. We take deep interest in any reasonable scheme for accommodating good medical practice to the means of the working classes, and we shall be glad to hear of the success of this particular experiment. We do not like to speak too critically, lest such experiments should be discouraged. It seems to us that the monthly fees for children—2d. (up to three, more than three are not to be paid for)—are too low. Another great omission is that of any rule for excluding unfit persons.

FOUL DUSTBINS.

To the Editor of THE LANCET.

SIR,—At an inquest held a few days ago on the body of a child who died at Lisson-street, Marylebone, the coroner, Dr. Hardwicke, commented strongly on the serious injury to health occasioned by the present system of allowing dustbins to remain in London and its environs for lengthened periods without being cleaned out. Perhaps you would bring your influence to bear on this matter, which certainly appears to me to require looking into.

An uncleaned dustbin, with its festering mass of decaying animal and vegetable refuse, particularly in hot weather and in crowded districts, is a grave evil, as anyone who has given the slightest attention to the matter of hygiene will allow, and the present system of having them emptied once in a fortnight is simply absurd. Of course, those who are addicted to cleanly habits can have their dust receptacles attended to oftener by entering into a private contract with the dustmen; but those whose means are straitened or who cannot afford this luxury, must be content to endure their pestilence-breeding bins, with all the foul odours and health-depressing influences attached to them, until such times as it may please the dustmen to give them a dirty clean out, the visits of these gentlemen being, like those of the angels, "few and far between" in the poor and crowded districts of this great city.

I have frequently been told by members of the working classes that it is no unusual thing for the dustbins in their neighbourhood to remain unattended to for months at a time; and when they appeal to the dustmen in charge of any passing cart, they are either laughed at, or met by a volley of abuse for their pains.

Surely such a state of things, which is easy of remedy, should not any longer be permitted!

Yours truly,

G. STANLEY MURRAY, M.D.

Meadowside, Putney, Sept. 20th, 1880.

MANUAL OF HYGIENE FOR INDIA.

THE following is the official notification of the prize offered by the Government of India for a "Manual of Hygiene," to which we have referred in a previous number of THE LANCET:—

"£100 PRIZE.—A prize of £100 is hereby offered by the Government of India for the best 'Manual of Hygiene' for the use of the British soldier in India. The work must be in clear and simple English, without theories, and thoroughly practical, showing the ordinary causes affecting health, the special dangers to health to which British soldiers are exposed in India, and more particularly during their first years in the country, and the best means by which these dangers may be averted. The work which, if accepted, will be printed at the public expense, and become the property of the State, must not cover more than 50 or 60 pages of print of small pica octavo size. Competing primers must be sent to the Secretary to the Government of India, in the Military Department, Calcutta, so as to arrive not later than the 31st March, 1881. Each should bear a motto, and have a sealed envelope attached, with the same motto outside, and the name of the author within. The prize will be adjudicated by a Committee, consisting of the Surgeon-General, Her Majesty's Forces in Bengal and Principal Medical Officer, Her Majesty's British Forces in India, the Sanitary Commissioner with the Government of India, and an Officer of the Quartermaster-General's Department to be appointed by his Excellency the Commander-in-Chief; but the Government of India will not award the prize unless a manual is produced in all respects suitable for the purposes for which it is required.

"ALLEN JOHNSON, Colonel,

"Simla, 16th July, 1880."

"Sec. to the Government of India.

J. C.—The letter contains no data upon which an opinion as to the nature of the case can be formed.—1. Our correspondent would have been perfectly justified in expressing to Mr. P. during the consultation, and to the friends in Mr. P.'s presence after the consultation, an opinion different from that of Mr. P.—2. There was no objection to his expressing an opinion of the case to the consultant.—3. We cannot see from "J. C.'s" letter sufficient reason for communicating with the coroner.—4. If the uterus was anatomically examined after death, and proved to have contained an ovum recently, a certificate stating the cause of death to be abortion would be false. Unless such proof was discovered, the certificate cannot be said to be false.—5. We cannot say whether the case should be reported in THE LANCET or not until we see the notes.

Mr. George Shaw.—The Students' Number of THE LANCET, Sept. 11th, gives the particulars required in full.

EXAMINATIONS AND THE EXAMINING BODIES.

To the Editor of THE LANCET.

SIR,—As one about leaving a large metropolitan medical school, may I be allowed to say a few words on the subject of examinations and diploma-granting bodies. I have, more especially during the last two years, had opportunities of mixing with men on the point of going up for their diplomas, have worked with them in the wards, in the outpatient department, and seen their ratio of marks at the test examinations, and so claim to have a more intimate knowledge of students than examiners or teachers at hospitals can possibly gain. I wish to speak now more especially of those who come to the hospital, and do as little work as possible, simply the compulsory appointments, take the easiest examination they can find, and then launch out into practice. Now, I say are there not many of these men who fail at the test examination of their hospital, and others who go up under protest and are plucked, three months after will leave London, and return full-blown physicians and surgeons (in the broad acceptance of the term), to the astonishment of their fellow-students? Given a man is through in Surgery at the College, I assert it is simply a matter of £ s. d. to obtain a medical qualification. Why do men leave London for an extra diploma, when studying at a metropolitan school, when what they require is within walking distance? Simply because the examinations are easier, and carry certain advantages with them; for it is an advantage to a general practitioner to style himself "Dr." The majority of the British public never will understand medical qualifications; there are too many of them. Now with 22,000 men on the Register, and still largely on the increase, I say it is high time something was done to make the test more equal. If questions of a difficult character are shown me as set for the written papers, I assert the answers many examining bodies require are of a very low standard. I am sure many men holding the senior appointments at hospitals will bear me out when I say it is terribly unjust, in these days of keen competition, to those who have worked hard to gain a good knowledge of their profession to see the number of men who slip through these loopholes, and at the same time know it is utterly impossible in the first instance for the public to discriminate between the two.

It is not for me to suggest a remedy; but I say it is the duty of examiners and the leading members of our profession to do something, instead of sitting mute and helplessly waiting for a Conjoint Scheme to be passed.

I am, Sir, your obedient servant,

September, 1880.

ALPHA.

Dr. Sargent, (Shadwell).—See the General Order of the Local Government Board respecting the appointment and duties of the vaccination officers. Section 10 of the Schedule attached makes provision for "tracking fugitives," as our correspondent terms it.

F.R.C.S.—We know of no recent means: only the old method of microscopical examination of the blood-corpuscles, and measuring their size.

Mr. James Startin.—In an early number.

GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—I would not have intruded on your space, but to make a remark on the concluding paragraph of Sir Thomas Acland's letter, published this day, is, I think, a necessity. He appeals to old Guy's men to rally together on October 1st, and to "judge for themselves whether there is any hindrance in respect of medical science, or observation, or practice in the way of the students or their teachers." Perhaps not. But are the treatment and necessities of the sick inmates secondary to these? I have always believed that these were of primary importance. Do not the bickerings of the governors tend to show the public that Sir Thomas Acland's view is one that finds favour in the board-room?

Yours truly,

AN OLD GUY'S MAN.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed. Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom. The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers. Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher. A First Issue is made each week at seven o'clock on Friday morning, for the Wholesale Houses only. A large Colonial Edition is also published for despatch the same day.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

Introductory Address

ON THE

MOTIVES AND METHODS OF MEDICAL STUDY.

Delivered at the commencement of the Winter Session at University College,

By J. BURDON-SANDERSON, M.D., F.R.S.,
JODRELL PROFESSOR OF PHYSIOLOGY.

GENTLEMEN,—The duty has been imposed upon me of occupying you, for half an hour or a little more, with words and thoughts which I must do my best to make useful to you. My subject is prescribed to me by the occasion. It relates to the fact that you are entering on the study of medicine—a calling which you have chosen, probably, on various grounds. Some, perhaps, because external circumstances favoured or compelled your becoming doctors; some, I hope, for the better reason that you have a liking for it.

There are two equally noble dispositions of mind which tend to render the profession of medicine attractive: one is the desire to lead a useful life—a life conducive to the happiness of others; the other, that mental quality which makes it a chief delight to investigate the phenomena of nature—to discover their order and relation to each other. These two tendencies may be called the practical and the scientific. They are alike noble, because each is equally exclusive of selfishness, and furnishes a man with a motive above and beyond the immediate object of making a living. To those who have chosen physic as merely the least disagreeable way of earning money within their reach, all that I can say is that medicine is a poor trade for an honest man; there are many others much more to the purpose. But to all who are actuated by either of those higher motives I have mentioned—to those who are either, in their measure, seekers after truth, or whose aim is to be useful to others, the assurance may be freely given that they will not be disappointed.

Let me first speak of the profession as a means of doing good to others. In this respect there is no other like it. Our work, though sometimes rough and requiring to be done in a rough way, is always beneficent. When in out-patient, dispensary, or union practice we have to come into daily relation with hundreds of men and women whose ailments we feel to be in great measure the fruits of their moral degradation, we are apt to find year by year our sympathies becoming weakened, and our work done rather for the sake of duty than for love. But even here abundant scope is given us for brotherly kindness. The patients in our hospital wards are not mere numbers, although for convenience we are in the habit of calling them so, but men and women whom we are trying to help out of their sad calamities. Our relations with them, however, are not to be compared with those which subsist between doctor and patient in private, and particularly in general practice. It is the general practitioner to whom above all other men the privilege is granted of really serving the sick. No one comes between him and his client. He is not only the healer, but also the adviser in questions concerning the nearest and dearest interests of his patients. Such powers of good doing (or, if they are abused, of evil doing) are not entrusted to anyone else in the community, and involve a great responsibility. There are some, I trust, among you who are beginning the study of medicine to-day to whom this responsibility is attractive. If that has been your motive in choosing your profession, you could not, I venture to say, have had a better.

But there is another noble reason for choosing the medical profession, one which has attracted to it some of its brightest ornaments. That motive is the love of science—or what is the same thing, the instinct of investigation, the desire to search out the secrets of nature; and I wish to show you to-day that this is also a worthy motive. I wish to show you that although the investigation of nature's secrets is not the business of the doctor, but rather the curing of human ailments, the instinct of investigation is a splendid motive for choosing the medical profession. And in order to do this I must ask your attention for a few moments to the relation

which subsists between the art of medicine, the business of doctoring, and the science which belongs to it, and has sprung out of it.

Whenever in the discharge of your future functions as doctors you have to find out what is the matter with a patient, in order that you may advise how he is to be cured, you will be guided in your conclusions by what is called clinical experience—i.e., by a collection of information about sick people and their ailments, which you carry about with you in your memory—information which you will have partly acquired by your own observation, but for the most part derived from the recorded observations of other people. As you go on in your professional life your store of this invaluable commodity will become richer and richer. If you have learnt any new practical expedient which is of value, you perhaps record it for the use and benefit of others, but, as a rule, clinical experience is like good deeds, its value ceases with the life of its possessor. A man can leave but a very small percentage of his hard-earned practical knowledge to those who come after him; yet, small as it is, it is by the accumulation of such contributions in the course of the last two centuries (for we need not go further back than Sydenham) that the modern art or method of medicine has grown; it is, in a word, the sum of the recorded experience of all the practitioners of medicine and surgery who have lived, since the necessity and advantage of systematically observing cases was recognised. The medical art is still progressing, and will continue to progress by this same method of slow accumulation. The mass of the knowledge which guides practice is still obtained almost exclusively by the comparison of new cases with old ones; but it has always been recognised by thinking persons that, sooner or later, medicine, in common with all other arts of civilised life, must gradually enter on a new era—that she, like the other arts, must seek a foundation for her practice in the application of what are called principles; in other words, that she must eventually depend upon a science, just in the same way as, for example, the art of navigation already depends on astronomy, or as the art of agriculture will some day depend on a knowledge of the physiology of plants. Much of the past history of medicine consists of the records of vain attempts to force on this result prematurely. It would be easy to show you how in the last century and in the first half of the present, system followed system, how theory after theory had its day or its decade, until some forty or fifty years ago it was discovered that all these theories were vitiated by a common fallacy—by the misconception that the functions of living beings are excepted from the operation of the general laws of nature, and in particular that the living and suffering human body is, as it were, a dynasty of itself, an *imperium in imperio nature*, the affairs of which cannot be discussed as if they were subject to the universal powers of matter. Until it was understood that, in so far as we know anything about him, man is part and product rather than purpose of the universe, there could be no science of medicine, as you will see at once if you place before your minds what are the subjects that medicine has to deal with, and what it is that constitutes a scientific knowledge of them.

Medical science means the knowledge of the causes of disease, and the mode of their operation—that is, the disorders they produce in the machinery of the living body. It includes also another closely related subject of scientific investigation, that which relates to the nature of remedies and the mode of their operation. As to the method of acquiring so much of this knowledge as can be acquired by you without encroaching on the time which must be given to the primary purpose for which you come here—the learning the technical part of your profession—I will speak immediately. My present purpose is to address myself for a moment to those who possess the scientific instinct, and have found out for themselves that truth is one of the two best things which exist in the world, and to try to show them that our science (I mean the science of medicine) is, irrespectively of its uses to mankind, as attractive in itself as any other branch of natural knowledge.

I have already given you a short definition of its scope, and I can make that definition even shorter. The purpose of all science, as you know, is the discovery of the relation of cause to effect, of agent to action. It is that which makes the difference between scientific knowledge and the knowledge we possess of matters about which we do not take the trouble to think. The subject of medical science is not merely human suffering and its causes, but these two in

relation to each other. The problems with which it deals are, therefore, as truly scientific as those of the other natural sciences, the difference between them being of degree, not of kind. Our knowledge about the way in which our bodies are acted on by things outside of us that do us harm—i.e., by the causes of disease or by the remedies which counteract them,—although it has grown with amazing rapidity in the course of the last generation, is scanty as compared with what it might be and with what it certainly will be a generation hence. The reason why I think so is that at the present moment new discovery as to the nature and causes of disease is being pressed forward in all parts of the world by every possible means. The processes of disease as they present themselves in the wards of hospitals, and the changes those processes leave behind them after death, are being observed with more minuteness and completeness than ever, while at the same time observations are being largely made on animals, having for their object to investigate the natural processes of disease by comparing them with those which are produced artificially or experimentally. In both of these directions, by both of these methods, the clinical and the experimental, men are striving after new discovery with an earnestness which has had no parallel at any previous period. In all the centres of medical learning new institutions are coming into existence—scientific observatories they might be called,—having for their sole object to investigate the nature and causes of disease. Earnest men are at work, year after year, unravelling some previously inextricable entanglement, or projecting the dry light of science into some dark and foggy corner. The progress is slow, and will probably continue to be slow for many years. The end must be gained by hard work and by that perseverance to which difficulties serve only as encouragements.

In speaking thus of the progress of discovery and of the hopes we entertain of the advancement of the science of medicine, I am sure you will not think that I am unduly occupying your attention with a matter with which it would be premature for you to concern yourselves. There is no fear whatever of your being beguiled into too early and too earnest a devotion to scientific study. Every influence which will surround you as students will be opposed to it, for it does not pay as a preparation for your future career as practitioners, and still less in the examination-room. I may therefore quite fearlessly say all that can be said in its favour. The purpose I have in view in doing so is to assure any of you who have the time and capacity for scientific study that it is not necessary to go out of your own subject—the science of medicine. You need not become zoologists or botanists, or even physiologists (excepting in so far as physiology is the threshold of medicine) in order to find the fullest scope for your powers of investigation. With equal ability and equal labour there is as much to be done in the way of new discovery in the science of medicine and surgery—that is, in the investigation of the cause and operation of disease-producing agents, and the mode of action of remedies, as in any other field of inquiry which can be selected, with the additional inducement that what is done for medical science is also done for humanity.

For it cannot be doubted that the possession of better knowledge as to the causes which produce disease and as to the conditions essential to the preservation of health, will enable the doctor to advise the community much more effectually than he can as yet on all matters concerning their bodily welfare. At present there are innumerable questions which concern the influence on the bodily health of the conditions under which we live, such as water-supply, food, climate, dwellings, and others, on which we find ourselves compelled to keep silence because they demand for their solution a more exact knowledge of the relations between man and the external world than as yet exists. Naturally enough, the public mistake our reticence for ignorance, and seeking for guidance elsewhere, accept any folly that may be presented to them, provided it is dogmatically asserted and has the semblance of a scientific theory. Considering that the external conditions of life influence human action at every turn, it is evident that if we knew more about the way in which these conditions act we should gain thereby a much more general influence. In the sick-room, the fact that the doctor is better informed than the patient and his friends, or is believed to be so, confers upon him for the time a power which is almost divine. But as regards the apparently simpler and more frequently recurring questions which relate to the ordinary *juvantia* and *lædencia* of daily life, we cannot claim the same superiority

of knowledge; and it is for this reason that in these matters the public are well content to do without us.

The moral of this is, that *if we want the power we must work for the knowledge*. It is without doubt most desirable as well for ourselves as for the community, that the medical profession should hold the position which belongs to it, and be looked up to as the source of knowledge in all matters medical; but this end is to be attained, not by scheming for political influence, but by showing that we are accomplished in our own science. The necessity for this is rendered every day greater by the gradual change which is now in progress in the higher education of this country. The relative number of laymen who are sufficiently acquainted with subjects allied to medicine to form an intelligent opinion on medical subjects and to detect the ignorance of pretenders, is year by year increasing. If, therefore, we are still to be leaders of the public in matters which concern their material interests, we must keep at least as far in front of them as we have done hitherto; and in my judgment the only way in which we can keep in front is by maintaining, alongside of that practical efficiency which has always distinguished the English medical practitioner, a high standard of scientific culture.

So much for the motives. Let us now consider the methods of medical study.

Everyone is familiar with what is meant by the three R's of elementary education. In like manner there are three P's in medical learning—Physiology, Pathology, and Practice, which comprehend all that you can desire to carry away with you as permanent acquisitions when you leave this place.

The relation of these subjects to each other is very simple. It arises from the consideration that as practice is to be the business of your lives, it must be in so far the end of your studies that the other subjects must derive their special interest for you from their connexion with practice. My object is to show you to the best of my power how much knowledge you may expect to acquire of these subjects, and how you may best acquire it in such a way as to retain it for good; for the first principle that ought to guide a man in study is to learn nothing to forget it. There are of course some facts which we are obliged to learn for a temporary purpose, just as we study a page of Bradshaw's Guide Book when about to make a journey; but in general nothing is worth acquiring that we do not intend to keep hold of.

Let me ask your attention first to the subject of Practice. The first thing to be said is, that the art of Medicine is one which requires much labour and long time to acquire. No man can hope to acquire it during the four years of his student life so as to be at the end of it an accomplished doctor. But the hospital offers you opportunities of learning the methods of practice which, whether you use them or not, will never recur in your after-life. As regards these opportunities, a great change has taken place, particularly in London, during the last half century—a change in the bringing about of which University College Hospital has played a principal part. Fifty years ago the hospital student had to teach himself everything. The only opportunity he had of learning how to examine a patient was by what was expressively called “walking the hospital”—that is, by perambulating the wards at the time of the daily visit. According to this plan, if the physician or surgeon took the trouble to think aloud, those more fortunate students who were next the bedside, if attentive and intelligent, learned something, but the rest nothing; and consequently, when this was the only mode of instruction, a man entered on his profession, in the majority of cases, with no better preparation for practice than the useful though ill-digested information he had picked up during his apprenticeship. Unfortunately, it still happens that some men—even University College men—begin their life-work ignorant of its duties; but for this they have to blame their own neglect, not want of opportunity.

You begin your hospital studies crammed with information as to the topography of the dead human body, which you have learnt in the dissecting-room, and with a certain, probably very inadequate, acquaintance with the living processes of which it was once the seat, but either entirely “green” as regards sick people and their ailments, or furnished only with such general notions as you may have picked up by occasional visits to the out-patient rooms or wards. The first thing you have to learn is how to observe the symptoms or signs by which diseases are

recognised, contenting yourself in the beginning with a very imperfect understanding of their meaning. Some of these signs are very simple, such as the frequency of the pulse, or the temperature of the body, requiring for their observation only attention and care; others are much more difficult, either because the eye or the ear requires to be educated to appreciate or distinguish them (as in the case of the sounds of the chest), or because they require acquaintance with particular modes of manipulation (examination of the urine), or skill in the use of certain instruments (e.g., the laryngoscope or the ophthalmoscope). Now, the plan of learning all matters of this kind used to be to blunder on by yourself until you succeeded. In this way no doubt some men learned better, but this advantage we are content to forego, considering that in consequence of the increased complexity of the technical procedures now in use, such a method would be impracticable.

Skill in any art is most easily and quickly attained by a combination of seeing with doing. Accordingly, the method by which you are taught the art of observing the signs of disease, which is the "beginning of wisdom" as regards medicine and surgery, consists in a combination of demonstration (that is, of showing how the thing has to be done) with what may be called "clinical drill" (that is, doing it under direction). The "clinical drill" consists of two sorts of exercise—one in which you make your observations in presence of your teacher and of your fellow-students, and state *viva voce* the results at which you have arrived; the other in which you make your observations by yourself, and hand the results to your teacher in writing: the two being complementary to each other as regards their respective advantages. The one teaches you promptitude, the other accuracy.

But to observe accurately and promptly is, as I said just now, only the beginning of medical wisdom. The next step in your preparation for practice is to concentrate the knowledge you have gained by the observation of signs, on the two practical questions you have to answer in respect of every sick person you have to treat—What is the matter with him? and What is to be done? This concentration we call, technically, making a diagnosis. How do you learn this? By methods analogous to those I have already described, in so far that your part of them is a combination of seeing with doing. In place of the very simple demonstrations given to a few men, by which you have learnt the art of observing symptoms, now come the clinical or bedside lectures, in which the physician investigates, before a much larger number, a complete case, *ab ovo usque ad mala*, and finally makes the diagnosis, and explains to you exactly the grounds of his conclusion, occasionally perhaps asking this man or that to verify some important matter of observation. The drill consists in this, that those students who have advanced sufficiently are asked to do by themselves what they have seen done, stating the facts and the conclusions they derive from them as regards diagnosis and treatment, for criticism. At the same time that you have learnt all this about internal diseases, you have acquired by similar methods a knowledge of the signs and diagnosis of injuries and other surgical affections, and have become more or less masters of the handicraft of surgical treatment; so that you now know not only how to find out what is the matter with a patient, but how to act on that knowledge.

A man so trained might be regarded as thoroughly equipped for professional life. But yet practical people will tell you that there is something wanting. And now let me say what that is. In University College Hospital there are numerous appointments which involve, along with residence in the hospital, more or less of the *responsible charge of patients*. It is wise to make the attainment of one or more of these positions (which I need scarcely say are bestowed exclusively as the reward of merit) from the beginning of your course the first object of your ambition, for a student who closes his medical career as house-surgeon to the hospital possesses what is of more substantial value to him than all the prizes, medals, or other distinctions he may have gained before—viz., the opportunity of learning how to face the actual difficulties of practice while still protected from the heavy responsibility of professional life. Unfortunately, these advantages cannot be placed within the reach of all who deserve them.

This is all that time will allow me to say about the method of learning medical practice. Let me now turn to the more difficult task of endeavouring to tell you in what way so much acquaintance with the science of medicine as lies within your reach is to be acquired. I will begin by stating

more definitely what I have perhaps already implied, that I believe it to be quite possible to practise medicine well without any knowledge excepting of that practical kind which I have just described to you—that is, the knowledge how to examine a patient properly, and how to apply the accredited remedies *secundum artem*. I believe it to be possible for an intelligent man, provided that he has learned sufficient descriptive anatomy to know his way about in the human body, to learn what he absolutely requires for practice by practice alone; and I would go further and say that if he had had efficient bedside teaching he would be much more useful to the public than a man who, without this, had gone through the most elaborate scientific preparation. It is possible (to quote the words in which Mephistopheles scoffs at medicine) to have "durchstudirt die gross' und kleine Welt," and in the end to be for practical purposes a fool.

I have already given you some general reasons for thinking that notwithstanding all this, it is desirable that you should know something of medical science, and I will now add another which is very cogent. No man, however practical the bent of his mind, refrains from speculating as to the nature of diseased processes. The most ignorant practitioner finds explanations of his patients' ailments in imaginary disorders of internal processes, such as those of digestion, secretion, and the like. Now, it is clear, that in so far as such speculations influence practice at all, they must influence it injuriously, and it is also clear that the only way in which they can be neutralised is by the furnishing of the mind with genuine knowledge. I may therefore assume that, if for no other reason, merely to guard himself from being misled by empty theories, everyone would desire to know something of the other two subjects I mentioned just now—viz., of Physiology and Pathology,—and the only question is how much of them you ought to try to know, and how they are to be learnt.

In entering on the study of human anatomy you make acquaintance with a subject which was before strange and even repulsive to you—the dead human body. By hard work in the dissecting-room the anatomical conception of the body as a system of bones, muscles, bloodvessels, nerves, viscera, becomes more and more familiar to you—and you know your anatomy. When you turn from anatomy to physiology and pathology, you have again before you the human body, but in a totally different aspect, which is quite as strange to you as the other was before. What you have to do with now is not the shape or appearance of the body, but only with its visible motions and with the invisible changes which go on in it and constitute its life. Now these visible motions are those of the muscles, and of the levers and pulleys which they act upon, or of the heart and of the liquid which it drives along a system of elastic tubes, or others analogous to these, all of which resemble those of machines. The invisible changes are, first those of organisation, changes which are associated with the development and growth of the organism and its parts; and, secondly, the innumerable and complicated molecular processes, unconnected with the formation of new structures, of which our bodily life in its essence consists—viz., the nutrition of the tissues, the secretion of glands, the contraction of muscles, the excitation of nerves and nerve-cells. This being so, it must be clear to you what sort of study the science which investigates these processes or changes in health and disease must be. It has to do almost exclusively either with the actions of machines or of molecules. It requires, therefore, of those who intend to pursue it, first, a knowledge of the nature of such actions; and, secondly, of the complicated structural conditions under which they are carried out in the living organism.

This being so you will see at once that to many of you the fact that your education, though otherwise excellent, has been of such a nature as to leave you in ignorance of the laws which govern the material world outside of you, is a serious obstacle in the way of your learning the science of medicine. And for this reason I would most strongly recommend you, if you know nothing of natural science, particularly of physics and chemistry, to set to work to learn the elements of them before you attempt to understand the much more difficult physics and chemistry of the living human organism. The knowledge of these subjects that you want in order to enter on the study of the science of medicine need not be extensive, but must be thorough and genuine, for it is not intended to be learnt and then forgotten, but to be retained and used. What you require, therefore, is to have appropriated as your own the explanations which science gives of the more simple relations which exist in the

inorganic world, in order that you may be prepared to understand the more complicated ones which present themselves in living beings. And this kind of knowledge experience shows to be directly proportional to the time and labour spent in acquiring it, and therefore, labour and time being limited, inversely proportional to its extent—i.e., to the number of things you attempt to learn.

The science of medicine—that is, all that you have to learn in addition to the technical knowledge you require for practice—relates, strictly speaking, only to diseases and their remedies, comprising pathology and pharmacology; but these subjects, as we have seen, are so inseparable from the larger subject—physiology—that the three must be considered as one, to the learning of which the same principle is applicable as to the study of the preliminary subjects. Your object should be not to store your memory with facts as they are called—these being often only dogmatic statements—but to understand the natural order of phenomena. This understanding you may gain by reading, and still better by attending lectures and demonstrations, but experience teaches that the knowledge so obtained does not become real until you have begun to observe for yourselves. The notions that you acquire without this are not only soon forgotten but, even during the short period that they are still sharply defined in the memory, are not believed in, and consequently the knowledge which is built up of such notions has something in it of the nature of sham. Now in the medical department of the college we have always done our best to guard against this, by developing to the utmost of our power the practical side of our teaching. It was in University College that the first course of practical physiology ever given in England was organised by Dr. George Harley, twenty-eight years ago, under the auspices of my illustrious predecessor in the chair of physiology. Since that time we have endeavoured year by year to advance in the same direction, notwithstanding many difficulties. One of the greatest of these was want of space—a difficulty which, I am happy to tell you, is now removed. In the new Science Wing we have been provided with magnificent working rooms, of such size that we can offer to each individual student a separate working place. In entering to-day on the occupation of these working rooms, it is right that we should express our gratitude to the Council, and to the generous contributors to the building fund, who have given us so noble a proof of their appreciation of the value of scientific teaching and research; and not least to the architect, Professor Hayter Lewis, to whose skill and foresight we owe so much in adapting the building to its purpose. This purpose is primarily practical instruction; but in addition to this the new laboratories will offer advantages not to be obtained elsewhere in London to all who desire the opportunity of working for the advancement of medical science by new investigation. To all such we bid welcome in the terms of our motto—"Cuncti adsint," venturing to hope, that however insignificant the means at our disposal may be, as compared with those of which Medicine can avail herself in other countries, our new physiological school may at some future time lay claim to the credit of having at least kept the lamp of science burning in expectation of the coming of a better day.

I have only a few more words to say. All of you know that since we last met on an occasion similar to the present we have lost one of the truest friends and most illustrious ornaments of this college—Dr. Sharpey.* I have already told you how the practical teaching of physiology was initiated by him. I wish to give those of you who never saw him some idea of what he was, and at the same time to give expression to my own feeling of veneration for his memory—of regret that we have lost him.

I cannot give you a true notion of Dr. Sharpey's scientific character without referring to the share which he took in the development of the science which he taught here. In 1836, when he was appointed professor, the sum of knowledge which existed as to the mechanical and chemical processes of the animal body was a mere rudiment of that which we now possess; but during the twenty years which followed that date, its growth was like that of infancy—it was more rapid beyond comparison than it had ever been at any previous period, more rapid than it can be again. This growth began with the revelation of the previously unknown organisation of plants and animals, which was the fruit of the discoveries of Schwann, and of the anatomical researches of Henle, Bowman, and Sharpey himself, and closed with the achieve-

ments in vital physics and chemistry of Helmholtz, of Ludwig, of Bernard.

The invitation of Dr. Sharpey to take a position so important as the chair of Anatomy and Physiology in this place had an influence in promoting the study of what afterwards came to be called Physiological Anatomy, which could hardly be exaggerated. The subject was new, and an expositor was wanted, and he was singularly fitted for the position which he was called to occupy both by nature and by education. By nature he was a man of extraordinary vigour, both mental and bodily, and at the time of his advent to London was in the strength of his youth with the best years of his life before him. He had prepared himself for the work of teaching by devoting several years to the study of anatomy in the schools of France, Italy, and Germany, and had cultivated his mind to the utmost by intercourse with the most active intellects of his time. He had already acquired a great reputation as an anatomist and comparative anatomist, and had an unrivalled acquaintance both with the literature of his time and with the writings of the older anatomists and physiologists, as well as with the historical development of the subject he was about to teach.

A man possessed of so wide a range of knowledge and endowed with so remarkable a judgment as he was, could not fail to be a great teacher. The excellence of his teaching consisted in its being the spontaneous outflow of a richly furnished intellect. To this were added other more personal qualities, which rendered it specially adapted to its purpose and to the audience whom he had to address. No man more thoroughly sympathised with the student or understood more instinctively his requirements; and consequently his lectures, while they satisfied those who sought for full knowledge, set forth the subjects taught with such clearness that even the least capable found it difficult to avoid learning something.

I must not dwell longer on the intellectual endowment of the dear friend whom we have lost. We shall not see his face or hear his voice again. We shall no longer have the opportunity of drawing for information on the exhaustless stores of his memory, or of profiting by his sage counsels. But to those of us who knew the moral excellences of his character, his inflexible devotion to duty, his perfect truthfulness his unwillingness to think evil of others, his ready sympathy with every noble and generous sentiment—his bright example, though he is gone, will still speak. Let us strive to follow it.

An Address

DELIVERED AT

KING'S COLLEGE

After the Distribution of Scholarships and Prizes at the Opening of the Winter Session,

By GEORGE JOHNSON, M.D., F.R.S.,

PROFESSOR OF CLINICAL MEDICINE AT, AND SENIOR PHYSICIAN TO, KING'S COLLEGE HOSPITAL.

LADIES AND GENTLEMEN,—The first duty that I have to perform in addressing you is a very pleasant one: I have to offer my hearty congratulations to those students who have been successful in obtaining scholarships, prizes, and other marks of distinction. Although many years have elapsed since the last occasion on which, in this room, I was amongst those to whom similar honours were awarded, I retain a lively recollection of the pleasure experienced while receiving them in the presence of near relations and friends. I can, therefore, very heartily sympathise with you on this occasion.

And now, exercising the privilege usually granted to advancing years, let me offer you a few words of advice. I beg of you not to consider these scholarships and prizes as the end and object of your labours; rather they are to be looked upon as incentives to yet further and more prolonged exertion. By the success which you have hitherto achieved you have shown that you possess an amount of intellectual capacity and of industry from which in after years much more will be expected; and in proportion to the pleasure and satisfaction which your friends have experienced in your

present success and distinction would be their disappointment and sorrow if in the future any of you should, unhappily, fall short of the hopeful anticipations which your past career has excited. If you go on as you have begun, persevering in habits of steady conscientious industry, a more or less prosperous and useful career may confidently be predicted for you. Our experience of the past leads us to anticipate that men who have distinguished themselves, as some amongst you have done, will rise to eminence in their profession—that they will not only become skilful, trustworthy, and therefore trusted practitioners, but that they will become teachers and leaders. It may fall to the lot of some of you to be enabled, by diligent and sagacious research, to throw light upon some of the as yet obscure phenomena and processes of disease, to advance our knowledge of the causes of sickness and mortality, and to add to and improve the means of prevention or of cure. If such should, happily, be the result of your labours, you will have the satisfaction of feeling that, not only have you gained deserved credit for yourselves and for your school, but you have conferred a lasting benefit upon mankind.

I may assume that there are some present who have been unsuccessful competitors for prizes or other distinction as there are unquestionably some who have not been competitors at all. To each of these classes I have a few words to say. My experience has taught me that there are some men of intelligence and steady industry, who, apparently from a want of the power to arrange their ideas in a methodical order, or to give a clear expression to them, fail in competitive examinations. Now while we cannot but condole with such men in their disappointment, we may encourage them to persevere by reminding them that the labour of preparing for even an unsuccessful competition is rewarded by an increase of knowledge, and that the facility of quickly arranging ideas and giving expression to them in a written or a *vivâ voce* examination is often much increased by practice. Let them not, therefore, despair of greater success in the future than they have met with in the past.

With regard to those students who refrain entirely from competition, while there are some who perhaps want the ability, and others who lack the industry which is requisite to ensure success, there are some men of unquestionable ability and industry to whom competitive examinations appear to be distasteful. I have known and could now point to some of these quite exceptional men who have proved their ability and their industry by the attainment of great success, as able and skilful practitioners, and even eminent teachers, but who never, during their student career, competed for a prize or a scholarship. Most of this class of non-competitors whom I have known have been men of ample means, for whom even the most valuable of our scholarships have had little or no pecuniary attraction; but for those less favourably circumstanced, whose friends may perhaps find a difficulty in defraying the expense of a complete and prolonged medical education, it becomes a positive duty to endeavour to lighten the burden of parents or guardians by a diligent effort to win a scholarship.

And here again I could point to several instances in which the gaining of our senior scholarship, with perhaps another from the University of London (an object of ambition which I trust that many of you are keeping in view), has enabled a persevering student to prolong his education in London, and ultimately to secure a permanent position here, which without such early pecuniary fruit of his own industry would have been unattainable.

I am not unmindful of the fact that for the first time, at a distribution of prizes in this College, we have here present a number of young men who are on the threshold of their medical studies; and to them in particular I now desire to address a few words of welcome, of counsel, and of encouragement.

No one who is interested in the career of a medical student can contemplate the weighty consequences to himself, to his family and friends, and lastly to mankind, of the manner in which he spends the four or five years during which he has to prepare himself for the practice of his profession, without a feeling of anxiety. And this anxiety is not lessened by the consideration that in this great city young men are exposed to many temptations, more or less perilous, the tendency of which, if yielded to, is to impair their moral and intellectual powers, and so to hamper and hinder them in the prosecution of their studies. The best safeguard against these dangers, next to those high principles and that sense of duty which we may hope that all have had instilled into

them at home and at school, consists, I believe, in an immediate and persevering application to the work prescribed for them by the curriculum.

The student who has arrived at that stage of his progress in which he has learnt to take delight in his work is happily safeguarded against many dangers that beset the idler, for whom it is proverbial that the author of all evil is always preparing some work of mischief.

The subjects to which your attention will first be directed are anatomy, physiology, and chemistry, and in order to obtain such a knowledge of these large and complex sciences as will form a secure basis for that acquaintance with disease and its preventive and curative treatment, which is the final and supreme stage of your medical studies, you will need to devote to them all the time, the attention, and the ability that you have at your command. The ablest and the most gifted amongst you will not find that he has any time to spare if he sets himself in earnest to master the many details and the underlying principles and laws of these extensive and important sciences; nor, on the other hand, need the duller and least brilliant student despair of a large measure of success if only he has inherited or acquired that essential qualification for the highest success in any great or useful calling—a habit of steady, persevering industry.

To borrow an illustration from the now veteran Thomas Carlyle, "All work of man is as the swimmer's. A waste ocean threatens to devour him; if he front it not bravely it will keep its word. By incessant wise defiance of it, lusty rebuke and buffet of it, behold how it loyally supports him—bears him as its conqueror along."

Every teacher of experience could point to numerous illustrations of the lesson inculcated by the fable of the hare and the tortoise—I mean examples of the brilliant and apparently highly-gifted idler being surpassed in the race of life by the comparatively dull but plodding and steadily industrious man. It would, of course, be unreasonable and absurd to deny that individuals and races of men differ immeasurably in the kind and degree of their inherited or acquired mental powers, but my argument is that without industry the most brilliant man will fail in any high pursuit, and that the greatest works of so-called genius have not been accomplished without great labour—*nîl sine magno labore natura mortalibus dedit*. The skilful artist who, with a few apparently easy and careless touches of the pencil, puts upon his canvas a beautiful scene of nature or a striking likeness of a living human face, has acquired this marvellous power of rapid execution only by long-continued study and by the diligent practice of the mechanical details of his art.

Again, the musician who thrills and delights an audience by his brilliant performance has obtained this admirable facility, this consummate skill, by years of laborious study and practice. An eminently-skilled musician must no doubt possess an innate highly and delicately-organised brain and nervous system. I have had frequent opportunities of observing the extreme nervous sensibility of eminent musicians,—a sensibility which, with a capacity for the intense enjoyment of their delightful art, carries with it also an exceptional liability to acute suffering. One phase of this subject is strikingly and amusingly illustrated by Hogarth's picture of "the enraged musician," who is represented as driven to distraction by the discord of street noises.

So of the poet, if the saying *nascitur non fit* be true, he must be born and cannot be made a poet; it is equally true that the greatest and most successful efforts of poetic genius are the results of the prolonged and diligent culture of inborn intellectual power. It has been said of Milton by an eloquent Hunterian orator¹ that if in the full maturity of his genius he—

"fed on thoughts that voluntary move
Harmonious numbers."

He had acquired this power, he had earned this facility, this spontaneous activity, by the industry with which in early life he had accustomed himself

"to build the lofty rhyme."

It would not be difficult to prove by numerous extracts from the dramatic works of Shakespeare that the most admirable productions of his unrivalled genius are the result of careful painstaking study and elaboration. As an illustration I select one passage, which has a medical as well as a literary interest. You are aware that there exists an early version

¹ Hunterian Oration, by Joseph Henry Green F.R.S.

of the play of "Hamlet," published in 1603, and that this was followed by a later edition, "enlarged," as the title-page states, "to almost as much again as it was." A comparison of the two editions affords many interesting illustrations of the manner in which the great dramatist had elaborated and improved upon his original rough sketch. The passage to which I refer is that in which Polonius describes the origin and progress of Hamlet's supposed madness. In the earlier edition Polonius says—

"He straightway grew into a melancholy,
From that into a fast, then into distraction,
Then into a sadness; from that into a madness,
And so, by continuance and weakness of the brain,
Into this frenzy which now possesses him."

In the revised edition we have the well-known lines:—

"And he repulsed, a short tale to make,
Fell into a sadness, then into a fast,
Thence to a watch, thence into a weakness,
Thence to a lightness, and by this declension
Into the madness wherein now he raves,
And we all wail for."

The improvement in this later version of the passage, the result of careful observation and study, is very obvious and striking. In the revised work such repetitions as "melancholy" and "sadness," "frenzy" and "madness," are avoided, and we have condensed into a few lines the perfectly correct medical doctrine that a great sorrow often causes in succession sadness, loss of appetite, wakefulness, weakness, "lightness," or slight and transient delirium, and at length raving madness; these phenomena occurring, as our daily experience teaches us, exactly in the order in which they are mentioned by Polonius.

More than one lecture might be given, and much has been written and published to illustrate Shakespeare's medical knowledge, more especially his unequalled mastery and marvellous exposition of psychological phenomena. Without doubt his powers of observation and imagination, and his command of language were incomparably great, but even these vast mental endowments would not have enabled him to produce such masterpieces of dramatic art as "Macbeth," "Othello," "Lear," and "Hamlet," without an industrious use of his unequalled intellectual powers.

If then it be true, as it appears to be, that for the attainment of success in the practice of the so-called *fine arts* of painting, music, and poetry, diligent study, and persevering industry are requisite, they are not less so for the acquirement of that scientific knowledge and practical skill which are essential for the successful practice of medicine and surgery.

The skill and the manual dexterity which enable the surgeon to perform successfully a difficult operation, guiding his knife safely amidst delicate tissues and vital organs, are not to be acquired without prolonged study and much practice. Nor, again, is that knowledge of the interdependence, or physiological relationship between various tissues and organs—their action and reaction upon each other in health and in disease—which often enables an experienced observer to base a diagnosis on a single phenomenon—it may be the character of the pulse, the visible throbbing of an artery, a patch of degeneration in the interior of the eye, the sound of the cough or of the voice, or the expression of the countenance—such knowledge, I say, can be obtained only by long and patient clinical observation and research.

One piece of advice I am anxious to impress upon you, which is this: whatever line of practice you may hereafter—whether by natural taste, inherited opportunities, or other favouring circumstances—be led to adopt, whether you become consulting physicians or surgeons, or so-called general practitioners, or whether you take up some such important special department of practice as obstetrics, the care and treatment of the insane, or ophthalmic or aural surgery, it would be an error and evil for you too early in your professional career to devote yourselves to the exclusive study and practice of any one department of medicine or surgery. The more general is your knowledge of disease, the more thoroughly you have become practically skilled in the use of every means of physical diagnosis, the better qualified will you be hereafter to undertake any special department of practice.

As a physician I gratefully acknowledge my obligation to my surgical colleagues for the lessons they are continually teaching me; but more especially I am indebted to my old master and friend and colleague, the late Sir William Fergusson, under whom I had the advantage to serve as dresser and house-surgeon. Then, on the other hand, I

venture to say that the most eminent and skilful of surgeons finds himself rather helped than hindered in his daily practice by an acquaintance with many details which are usually considered to come within the province of the physician.

I have often said, and I repeat now, that some of the best practitioners whom I have the happiness to know are what are called "general practitioners"—men equally at their ease and equally skilled in setting a broken bone or conducting a patient safely through the crisis of a fever. These men are usually the confidential family advisers in all emergencies; and while pre-eminently the friends of the poor, often associating on equal terms, as their intelligence and culture entitle them to do, with the best families in their neighbourhood. There are few positions in the profession of greater honour and usefulness than this.

Then, *per contra*, some of the worst and least trustworthy practitioners, although perhaps highly patronised by an indiscriminating public, have been men with an unmerited reputation for some small speciality. A large proportion of the public adopt and act upon opinions with regard to special departments of practice the exact opposite to those which we believe to be reasonable and right. Instead of assuming, as we do, that for a complete knowledge and successful treatment of any one class of disease a general acquaintance with the whole range of pathology is requisite, they appear to suppose that skill in one department of practice implies ignorance of every other. As an illustration of this, the late Dr. Latham related the following anecdote to Sir Thomas Watson, from whom I heard it:—

Dr. Latham, as many of you are aware, was a very eminent, learned, and accomplished physician of St. Bartholomew's Hospital, but he happened to have published more on diseases of the heart and lungs than on any other medical subject. A patient of his, who had recently recovered from some pulmonary affection, one day addressed him thus: "I feel that as regards my lungs I am quite well, and now I think of going to consult Dr. Watson about my general health." To which Dr. Latham replied: "Yes, I see; in your estimation, then, Dr. Watson is an 'architect,' and me, I suppose, you look upon as a bell-hanger." It is our wish—the wish of myself and my colleagues—that all of you who are now entering upon, or who have already made some progress with your medical training here, should aim at qualifying yourselves to be architects and not mere bell-hangers in the profession.

In the study as in the practice of any profession or calling it is well to keep steadily in view a high standard of excellence, and, by continued effort, to endeavour to attain it.

"We live by admiration, hope, and love,
And, even as these are well and wisely fixed,
In dignity of being we ascend."

In our great metropolitan cathedral you have seen or you may see the fine and impressive monument to Nelson, in which Britannia is represented pointing the upward gaze of two young midshipmen to the great admiral as a model to be admired and imitated. In like manner, and with a like purpose, let me direct your attention to a former professor of medicine in this college as happily a living example of a truly great physician. I refer, of course, to Sir Thomas Watson, as a man not only learned in the science and skilful in the practice of his profession, but a gentleman in the fullest sense of the term—remarkable not less for the courtesy and consideration uniformly shown to his professional brethren than for the care and skill bestowed upon his patients. His published lectures on the Principles and Practice of Physic have for the last forty years continued to instruct by their practical wisdom, and to charm by their lucid and scholarly style. And now at an age of more than fourscore years he enjoys the well-earned and cheerfully rendered respect and esteem of the entire profession, and of all classes of the public from the Sovereign downwards. He possesses "that which should accompany old age, honour, love, obedience, troops of friends." That, gentlemen, is the high standard of excellence towards which I would urge you all to strive, and to which it may be that happily for yourselves and for mankind some of you may attain.

And now I propose to conclude this brief address with a quotation from the discourse by which Sir Thomas Watson prefaces his course of lectures on medicine. The passage which I am about to quote will be familiar to many of you, but to most of the younger part of my audience it will probably be new, and it may serve, by its eloquent and impressive language, to convey to them a just idea of the real

nobility of our profession and of the principles by which we should be guided in the study and practice of it. In the earlier part of the lecture the professor sketches the general plan and outline of his course, he indicates the purpose and the limitation of teaching by lectures, and after referring to the duties and responsibilities respectively of the teacher and of the student, he concludes his lecture thus:—

“But with all its responsibilities, both for teacher and for learner, the profession which you and I, gentlemen, have chosen, or which circumstances have prescribed to us, is a noble profession, and worthy the devotion of a lifetime. If you fit yourselves now for its high functions, and pursue it hereafter in earnestness and truth, it will probably conduct you to an honourable competence, and it will assuredly prove a salutary school of mental and of moral discipline. Trials, no doubt, and difficulties, belong to it, but it has also privileges and immunities peculiar to itself. Affording ample scope and exercise for the intellect, it is conversant with objects that tend to elevate the thoughts, to temper the feelings, and to touch the heart. I have already reminded you how it brings beneath our minute and daily notice that most remarkable portion of matter with which the human spirit is here mysteriously tabernacled, and which, apart from that singularly interesting thought, awakens increasing wonder and admiration the more minutely we investigate its marvellous construction. The sad varieties of human pain and weakness with which our daily vocation is familiar should rebuke our pride, while they quicken our charity. To us are entrusted in more than ordinary measure, opportunities of doing good to our fellow-creatures, of showing love towards our neighbour. Let us beware how we idly neglect, or selfishly abuse, a stewardship so precious, yet so weighty. The profession of medicine having for its end the common good of mankind, knows nothing of national enmities, of political strife, of sectarian divisions. Disease and pain the sole conditions of its ministry, it is disquieted by no misgivings about the justice or the honesty of its client's cause, but dispenses its peculiar benefits, without stint or scruple, to men of every country and party, and rank and religion, and to men of no religion at all; and like the quality of mercy, of which it is the favourite handmaid, ‘It blesseth him that gives, and him that takes,’ reading continually to our own hearts the most impressive lessons, the most solemn warnings.

“It is ours to know in how many instances, forming, indeed, a vast majority, of the whole bodily suffering and sickness are the natural fruits of evil courses, of the sins of our fathers, of our own unbridled passions, of the malevolent spirit of others.

“We see, too, the uses of these judgments, which are mercifully designed to recall men from the strong allurements of sense and the slumber of temporal prosperity, teaching that it is good for us to be sometimes afflicted. Familiar with death in its manifold shapes, witnessing from day to day its sudden stroke, its slow but open siege, its secret and insidious approaches, we are not permitted to be unmindful that our own stay also is brief and uncertain, our opportunities fleeting, and our time, even when longest, very short if measured by our moral wants and intellectual cravings.

“Surely, gentlemen, you will not dare without adequate and earnest preparation to embark in a calling such as this, so capable of good if rightly used, so full of peril to yourselves and to mankind if administered ignorantly or unfaithfully. And even when you have made it, as you may, the means of continual self-improvement and the channel of health and of ease to those around you, let not the influence which you will thus obtain beget an unbecoming spirit of presumption; but remember that in your most successful efforts you are but the honoured instruments of a mightier Power—that, after all, ‘it is God who healeth our diseases and redeemeth our life from destruction.’”

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—The society met on the 1st inst., for the election of office-bearers for the session 1880-81. The following is the result:—President: Dr. George Buchanan. Vice-Presidents: Dr. D. Taylor (Paisley), Dr. J. B. Russell. Council: Dr. Alex. Robertson, Dr. A. L. Kelly, Dr. Bruce Goff (Bothwell), Dr. Geo. Willis (Baillieston), Dr. Geo. Mather, Dr. H. C. Cameron, Dr. Robert Forrest, Dr. Lapraik. Secretaries: Dr. Joseph Coats, Dr. W. L. Reid. Treasurer: Dr. Hugh Thomson.

ABSTRACT

OF

Introductory Lecture

ON THE

EDUCATION OF THE GENERAL PRACTITIONER.

Delivered at St. George's Hospital, Oct. 1st, 1880,

By JOHN CAVAFY, M.D., F.R.C.P.,

ASSISTANT-PHYSICIAN TO THE HOSPITAL.

AFTER some preliminary remarks on various changes in the staff, especially the loss sustained by the resignation of Mr. Pollock, the lecturer proceeded as follows:—

I have endeavoured to consider on what subject your attention may for a short time be occupied, without being fatigued or repelled; and I have chosen the old topic of medical education. It is of the greatest importance to all of us, and of perennial interest; and though it is as old as the medical schools in which it is carried out (or rather as old as medicine itself), it is as new as the latest modification in teaching and examination which the exigencies of modern times have required.

Premising that what I am about to say is not intended to have any reference to the training required of candidates for university degrees, I purpose to consider, shortly, what form of education should be given, and what subjects should be taught to those who intend to practise the whole of the medical art—i.e., general practitioners. To this class, so far as knowledge goes, I hope we all belong, whether we be physicians, surgeons, or specialists. For there is now a far closer connexion, a greater approach to unity, between the various branches of our profession than appears to have obtained in the good old times. The surgeon of the present day is not simply the possessor of a special form of manual dexterity; he is rather a physician who operates. Again, a physician cannot, I hope, be defined as a practitioner who is ignorant of surgery; while those who ultimately confine their practice to special departments will be the first to acknowledge that this limitation would be next to impossible, were they not previously possessed of a wide general knowledge of their profession. In short, the science and art of medicine are logically one and indivisible; and there is no strict line of demarcation between the various subdivisions which have become established as matters of social convenience.

The general practitioner, who possesses the advantage of being concerned with the whole of his profession, may fairly be taken to be the typical “doctor” of our day. He has developed rapidly within a comparatively recent period from the imperfect or larval condition of the old apothecary; and although he may be said now to have passed through his last metamorphosis and to be a complete imago, as it were, traces of the earlier and less perfect state (such as the selling of medicines) may be still occasionally observed in him. Both his general and professional education, however, have improved enormously, and there can be no doubt that so far as social position and influence are concerned, the practitioner of our own day holds a far higher place than that of the old apothecary, from whom he has sprung. We now find among general practitioners men of the highest general and professional cultivation, often possessing university degrees, sometimes men of profound learning; members, in short, of a liberal profession.

In the old days, when general and professional education were not attainable with the same facility nor to the same degree as now, it might fairly be said that the apothecary was a nondescript tradesman. His surgery was called “the doctor's shop,” a term which probably survives in remote country districts. In this shop knowledge, it is true, was one of the commodities sold to the public; but pills and potions, powders, plasters, and ointments, “doctor's stuff,” in short, formed the chief portion of the stock-in-trade. His knowledge, however, if limited, was often excellent of its kind. It was gained during a long apprenticeship, followed by a brief period devoted to the process known as “walking

the hospitals." As "he who runs may read," so no doubt he who walks may learn; and in one way or another the apothecary (the word, by the way, means "a shopkeeper") became possessed of much knowledge, which he was fond of calling practical, and of a number of useful knacks which stood him in good stead. So far as science is concerned, anatomy, and the little that was known of physiology, were not dead letters to him. He knew a little chemistry, and perhaps more botany. But that which he knew best was not science at all, but the exercise of his art. He could set a fracture, reduce a dislocation (nearly always), and conduct a case of labour which presented no great difficulties. He could handle his lancet with a skill and freedom which gave great satisfaction to his full-blooded patients. He could make pills, not so well perhaps as a modern pharmacist, but probably better than most of those in this room; his plasters were evenly spread, and his mixtures cunningly compounded with due attention to sweetening and colouring ingredients. He had a very fair clinical acquaintance with common illnesses, which he treated according to a tolerably uniform plan of purgation; and, it must be admitted, with a fair measure of success. He was further credited with skill in the art of managing his patients—an art to which the practitioner of our day continues to attach much importance. I have never quite understood what this means; but I presume it must refer to some trick of manner, or mode of address, which he expressly adopted, and perhaps varied according to circumstances; a shake of the head, a frown, a smile, an assumed look of wisdom, an air of grappling with a mental problem: all these things are not without influence on patients when judiciously employed, and may still be tested by anyone who cares to do so. If we add to the above attainments a modicum of common-sense (a variable quantity), I think we shall have completed the equipment of the old-fashioned surgeon and apothecary. It must be admitted, I think, that so far as practice is concerned he was not badly off; what he knew, he knew thoroughly; he had learnt it by doing; by seeing, hearing, touching for himself; and constant practice had given him dexterity and confidence.

Now, if we take the practitioner of the present time, and compare his attainments and the manner in which they have been acquired, we are at once struck with three things.

The first is that he has been taught a vast number of subjects which were never dreamt of by the old apothecary, probably because they did not exist in his day. The student now learns many branches of natural science which have only come into existence as it were yesterday, which have developed with unparalleled rapidity during the present century, and which are still in a state of active, almost violent, growth. The whole of modern chemistry and physiology, histology, pathology, and morbid anatomy have arisen as more than rudimentary sciences only within the most recent times.

In the second place, the purely professional subjects, medicine, surgery, midwifery, and all those subdivisions which are called specialties, have attained a development which has practically revolutionised the medicine of past times; but which has also enormously increased the difficulty of imparting to the student more than mere rudiments, especially if we include such comparatively new subjects as medical jurisprudence and hygiene.

The third point which strikes us is that the manner of learning has of necessity changed. It is related of Sydenham that on being asked by a beginner in medicine what books he should read, he replied: "Oh, read Don Quixote, it's a capital book. I read it myself, often." Probably Sydenham meant that the medical literature of his time might be neglected entirely without disadvantage, but he may also have intended to disparage reading altogether as opposed to observation. What would he say now could he come among us? Would he continue to consider Don Quixote as forming a sufficient medical library, or would he admit the inevitable, and, however reluctantly, himself compose a text-book for students? Whatever conclusion he might come to, the fact remains that the student of the present day gains, and must gain, much of what he knows or thinks he knows by

"poring over miserable books."

This cannot be avoided with the multiplicity of subjects to which the student is expected to "give his mind," as it is called, and on which he is periodically invited by examiners to "do papers." It is, indeed, in this process of doing papers that the value of mere information, as distinct from real knowledge, is chiefly shown. A candidate may

fill sheet after sheet with creditable matter, and yet remain ignorant of the most elementary points when the actual things themselves of which he has been writing are brought under his notice. Let me give you one or two examples. At a recent examination in natural philosophy, the candidates were asked to describe a vernier, an instrument for estimating fractional measurements. The written answers were admirable descriptions of the apparatus in question. At the *vivâ voce* examination, among other things, the students were shown a vernier. Not one of them knew what it was. Again, at another examination, a gentleman showed the widest acquaintance with his subject (a branch of natural science) so long as he was confined to writing about it. "He did a good paper," as the phrase goes; but he failed to recognise one of the simplest tissues when this was shown him under the microscope.

In neither of these two instances (and similar ones no doubt occur to many of my hearers) can we say that true knowledge had been acquired. Knowledge is familiarity with things. Information may be no more than a memory for words. Knowledge once acquired is fixed and permanent. Information is deciduous, and is often finally got rid of in the examination room.

Now it is sometimes complained, with some show of justice, that we furnish you with too little knowledge and too much information; that we enable you to pass examinations, but that after these are done with the successful candidate is sometimes singularly incompetent even in rudimentary practical points connected with his profession. He may be a graduate in medicine of a university, and yet he may introduce a pessary into the rectum; he may have gained medals and prizes, and yet be unable to prescribe, to apply a bandage, to make a splint.

I believe that there is a certain measure of truth in the assertion, but I also believe that the difficulty has been recognised, and is in a fair way to be removed. It is, in part, due to the short time which is now devoted to the study of medicine, a time which is too largely taken up by the collateral sciences. Our old-fashioned apothecary occupied at first no less than seven years in the study of his profession—five years of apprenticeship and two of hospital study; and although later this time was shortened, there still remained five full years devoted to learning, the things to be learnt being fewer and simpler by far than those the modern student is supposed to master.

Now, instead of five years, we have less than four as the minimum time required to obtain a qualification. Of this short time about half is taken up by subjects preliminary to medicine. Their mere number is appalling: osteology, chemistry, anatomy, physiological chemistry, histology, practical chemistry, botany, materia medica, all these have to be attended to by the student in his first year, while physiology and a second course of anatomy occupy the second winter session. If we add the time given to dissection, to pharmacy, and to attendance on surgical practice, we must admit that the strain is very severe upon all who have not an exceptional brain-capacity, and I am not aware that the hats of medical students are bigger than they used to be. The new student is not unnaturally bewildered by the multiplicity of subjects to which his attention is invited, subjects entirely new to him, and for which he has not been in any way prepared by his previous training. It is no matter for wonder if the result is often unsatisfactory and confusing, and if the student, rushing as he must do from one subject to another, finds that he is left with a mere nebulous cloud of information, when his mind is not actually dislocated by the violence of his intellectual antics.

That we have to do with a real difficulty, with no fanciful hardship, has, as I have said, been recognised, and various suggestions have been made as to modifications which it would be desirable to introduce in the scheme of our teaching. These are: to abandon some subjects altogether, to teach others with less elaboration, or to remove instruction in certain topics to a period anterior to the commencement of professional study.

The last plan has met with the support of the Medical Council, and the first of the licensing corporations to adopt it has been a learned body which will not be suspected of any tendency to rash reforms—the Royal College of Physicians. In March, 1880, new regulations were issued, according to which the licence will be granted to those who begin their professional education after this date, on passing three examinations, instead of two, as heretofore. Another examination! This sounds like the imposition of an addi-

tional burden on the already over-weighted shoulders of the student, but we shall see directly that it is an excellent measure of relief.

The subjects of the new first examination are—chemistry and chemical physics, materia medica, medical botany and pharmacy, and, lastly, osteology. The range of the subjects is defined in schedules issued by the College. Now comes the important point. Candidates may present themselves for the examination immediately after registration as medical students on producing evidence that they have "received instruction" in the subjects in question, the mode and duration of such instruction being, with a wise latitude, left unspecified. It is therefore possible for a student to pass this examination before he begins regular work at a medical school.

Now, from the mere point of view of saving time, the gain to the student who can do this is immense. Taking lectures only, I find that there is a gain of 168 hours (or twenty-eight working days of six hours each) which would otherwise be passed in attendance on them. While if we add, as we should do, the time given to practical chemistry and pharmacy, and, further, the time occupied in reading text-books, we may estimate the whole time gained as three months at the very least. But there is another advantage of more importance than any mere saving of time—the freeing of the mind from the strain and worry caused by the necessity of devoting a nearly equal attention to a large number of novel subjects, and the possibility of immediate and exclusive concentration on the all-important subjects of anatomy and physiology. Probably some time must elapse before these advantages become sufficiently known and appreciated to be generally adopted by intending students of medicine; but the benefit is so distinct and unquestionable that their recognition cannot be long delayed; and then we shall have to inquire as to the best mode of imparting the necessary instruction, and the best time for doing so.

I think physics and chemistry, perhaps botany as well, might be sufficiently taught at school, where the last year of scholastic life might be profitably occupied by instruction in the above sciences to those who are intended for the medical profession. With existing arrangements, there may perhaps be a little difficulty about this at first; but the days have gone by in which a head-master viewed with jealousy and distrust the introduction of a modicum of scientific teaching as a part even of the recognised school curriculum. Natural science is taught already at many of our chief public schools, and it will probably become the rule rather than the exception to find the subjects comprised under this term occupying much of a boy's time during the last year of his pupilage, if not earlier.

It may be that this cannot be done without abandoning to some extent the last touches of that classical training which has hitherto been held to soften the manners of boys. If this were true, it would perhaps be matter for regret. But "every schoolboy knows" that, with occasional exceptions, he and his fellows are hardly to be taken as examples of very profound scholarship. Of Greek I will say nothing; but taking Latin only, we find that the attainments of the average boy are not much more than the ability to construe a simple Latin author (*with* a dictionary), to write perhaps a few halting verses. He may have an imperfect acquaintance with Horace and Virgil, and will know some scraps of Roman history. Most probably he will have completely mastered those curious facts concerning Balbus, which were insisted upon in my own boyhood; but neither the schoolboy nor his teacher will seriously consider these simple accomplishments of sufficient importance to entirely prohibit attention to the graver matters with which science is concerned. For my part, I would willingly see the teaching of Greek and Latin extended and perfected, especially in the direction of comparative philology; but if we are forced to choose between what is usually learnt of them now and what *might* be taught of natural science, Balbus must go to the wall! Surely the faculties of observation, of sustained attention, of concentration, of accuracy, must be trained as effectively by a lesson in natural science as by the recitation of a few rules of grammar, or the uncouth translation of a phrase or two from a classical author; and if, at the same time, a boy became interested in his work (as he would in the hands of a skilful teacher), is not this awakening of curiosity, of a desire for knowledge, better than the apathetic indifference, or the hatred tempered by fear, with which so many boys undergo the usual classical training?

The remaining subjects comprised in the first examination

are purely technical, and might be studied during the period which elapses between a boy's leaving school and his registration as a medical student; or after registration, if entry at a medical school were to take place at the beginning of the summer session. Materia medica, botany, and pharmacy are taught at this time, and it would be easy to arrange that there should be a summer course of osteology. Practical chemistry is also taught during the summer session; so that to a student beginning his work on the first of May, the only subjects with which a previous familiarity would be requisite are theoretical chemistry and physics.

But with regard to botany, materia medica, and pharmacy, my belief is, that with the exception perhaps of the last-named, they have lost much of their importance. All necessary knowledge of drugs, and more, may be acquired during the instruction in practical pharmacy which we must still admit to be needful so long as doctors dispense their own medicines. This work, however, is gradually passing into other hands, those of the chemist and druggist. Many practitioners now prescribe but do not dispense; and when they do, often have a private dispenser. Besides, it is becoming daily more common for mixtures, tinctures, pills, all the compounds in short of the Pharmacopœia, to be bought ready made. All that remains necessary is to weigh and measure the requisite quantities. There is, I believe, an impression with some that the study of anatomy tends to burden the memory with a vast number of minute numerical and topographical details, tiresome and difficult to acquire, easily forgotten, and inapplicable to any useful purpose beyond the passing of examinations. But I do not see any possibility of altering the instruction in this subject which is now given. Anatomy has been studied and taught for centuries; hence its teaching both in method and in matter is more nearly perfect than that of any other branch of medical study, and there is no doubt of its value as a mental discipline. Then it forms a body of knowledge which is complete in itself; an organic whole; consequently it is not possible to omit any part as of less importance than the rest without serious damage to the whole fabric. Such a course would be paralleled if, in teaching a child the alphabet, we were to omit those letters, such as x and z, which occur infrequently and are used sparingly in the formation of words. Complicated and unimportant relations of parts; weights and measures of minute organs; all these, and much that is similar, are mere pedantry, and should be abandoned.

Microscopical anatomy, however, might, I think, be much simplified. If a student is acquainted with the main points of the minute structure of the simple tissues and of the more important organs he knows enough, even if much be omitted that has been brought to light by the labours of modern observers.

The importance of physiology cannot, I think, be exaggerated, although it will be long before it can be taught as fully and completely as it should be. It is, as Dr. Michael Foster pointed out in his recent admirable address at Cambridge, closely related to, or rather identical with, pathology; as he says, the two can no more be separated than meteorology can be divided into a science of bad weather (the normal condition) and a science of good weather. No step can be taken in pathology without constant reference to physiology. How can we understand, for instance, the heat, redness, pain, and swelling which form the grosser characteristics of inflammation (a process which underlies nine-tenths of the phenomena of disease), without reference to the capillary circulation, to the vaso-motor system of nerves, to the contractility of colourless corpuscles? Again, is it not self-evident that the high temperature which characterises the process of fever can only be understood or studied by a constant comparison with the conditions which govern normal animal heat? If it be said that all this has no immediate bearing on the recognition and treatment of disease, I would answer that no one who has the care of a patient can avoid forming some kind of conception as to the malady he is suffering from; and that he who possesses a knowledge of pathology and physiology will be more likely to draw correct conclusions than he who is ignorant of all but bare practice; often

"Most ignorant of what he's most assured."

Whether we like it or not, medicine as an art is becoming daily more and more dependent upon science, and it is difficult even to understand some modern discoveries of immediate practical importance without a fair knowledge of physiology and physiological methods. Of this I can give you an instance. Of late years the attention of investigators has

been much attracted to the pathology of contagion. The researches of Klein and Sanderson in this country, of Klebs, Chauveau, Pasteur, and many others abroad, have rendered it extremely probable that all communicable diseases are, if not immediately caused by, inseparably connected with, the development within the animal body of extremely minute vegetable organisms of the very simplest possible type. We do not yet actually know this with certainty in all cases, but it is quite beyond doubt in many; and in one instance, the splenic fever of cattle (which is communicable to man as what is called malignant pustule), the whole life history of the minute fungus, the *Bacillus anthracis*, is known with tolerable accuracy. It has been removed from the bodies of affected animals, cultivated in simple chemical nutritive fluids, and has then reproduced the original disease in animals inoculated with it. According to a recent report of Dr. Greenfield, the bacillus, if cultivated in a succession of chemical nutritive fluids, gradually loses its virulence, until, in about the fifteenth generation, it no longer produces any effect on inoculation. But there is a point midway between the fatal activity of the first and the inertness of the last generation, when the bacillus still produces the disease, but in a mild modified form, which is no longer dangerous to life. It is well known that one attack of any of the contagious diseases to which I have referred almost always protects against another; and it is therefore probable that inoculation with the mild form of the virus of splenic fever will protect cattle from the severe and fatal disease. I need not point out the hope this holds out to us that we may ultimately be able to control, in this or in some similar way, the majority of the acute contagious diseases which afflict mankind. If we should ever succeed in this, let it be remembered that so great an advance is due, not to clinical observation, not to the accidental discovery of some new drug or novel mode of treatment, but to the researches of the physiologist and experimental pathologist; to the botanist, and probably also to the chemist, who will help us by the study of so familiar, but so recondite, a process as putrefaction. The above research is an example of what we may hope will be gained by the application of purely physiological methods of investigation to disease; but we must not forget that we have already received from this source the antiseptic treatment of wounds, to which the great and beneficent art of surgery owes many of its most brilliant successes.

For the learning of medicine (I use the word in the widest sense) the two years which are left after the primary examination is over are not enough, because a lifetime is not enough. Experience and practice can only be acquired in the course of time. But if the two years are properly employed it is possible to master the elements of diagnosis, prognosis, and therapeutics, sufficiently to make future experience bear fruit. And here there is no flaw to be found in our teaching; what with dresserships and clerkships, work in the wards and in the dead-house, it is the student's own fault if he does not learn. You may get your information how you like, from lectures or from text-books, but your knowledge can only come to you by the constant exercise of your own faculties of observation and reasoning. It is our aim and our duty as teachers to enable you to leave us with your faculties so cultivated as to make your future experience worth having, for you will admit that all experience is not of equal value. The experience of a blind man is worth less than that of one who can see, and may do no more for him if he attempts to walk by it than lead him into a ditch. It is our endeavour to open your eyes, to furnish you with as true a conception of disease as is possible with our present knowledge, and to give you something of a critical faculty. If you possess this you will be able to estimate with fairness the value of many apparent novelties in your art, you will know when to accept and when to reject. But if you are without this power of discrimination you will be either at the mercy of every *ignis fatuus* which arises, or you will be at the other extreme, wrapped in impenetrable scepticism and unable to take advantage of real improvement.

If, on leaving us, you are unacquainted with "the routine duties of general practice," common sense and common attention will teach them to you in a very short time; if you do not know "the art of dealing with patients," try to do without it. I am very much mistaken if you will not find sympathy sufficient to replace it. You will, at the end of your career with us, know a great deal more than your medical forefathers; you will know it, I hope, thoroughly,

not as information merely; and it is far more important that you should know as much as you can learn of medicine, than that you should be specially trained in the exercise of those secondary arts, over which a few months' professional life will give you a sufficient mastery.

EXTRACTION OF A REVOLVER BULLET FROM THE SKULL.

BY SAMPSON GAMGEE, F.R.S. ED.,
SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

(Concluded from page 538.)

UNDER the heads of Diagnosis, Extraction of the Bullet, and After-treatment, I purpose concluding a concise history of this case.

Taking into account the inflammatory swelling on the left side of the neck and face, and the alleged firing of the revolver into the right ear, the patient's tranquil state twelve hours after admission was very remarkable. The revolver was a six-chambered one; three cartridges remained in it; and the statement, that two shots had been fired at someone, was borne out by finding two bullets on the floor of the room in which the patient was said to have shot himself. Reliable witnesses testified to hearing the third shot fired, but that bullet could not be found. Where the patient fell a good deal of blood was found on the floor, and it poured distinctly from within the right ear when he was brought to the hospital, and for some time afterwards.

When on the third day I examined the case under ether, the perfect integrity of the meatus was noteworthy. So soon as I penetrated the dilated passage with my little finger, the roughened and uneven edges strengthened, almost to demonstration, the presumption that the bullet had passed in; but it was only after considerable difficulty that I obtained this mark on the porcelain bulb of the Nélaton Garibaldi probe:—

The mark was distinct and shining black, and I preserved it as a fixed diagnostic sign; determining to use another porcelain probe for subsequent exploration.

It was now clear to my mind that we had to deal with a compound fracture of the temporal bone and an impacted bullet. The patient was calm, and wished that an endeavour to save his life should be made. In his then state, death was inevitable; and if extraction could be effected without much violence there was a bare possibility of recovery.

If any attempt was to be made, now was the time. To wait for symptoms of cerebral mischief was to throw away the only chance, small though it might be. My colleagues in consultation obtained an independent lead mark on the porcelain probe which they used, and unanimously approved my proposal to attempt the extraction. I soon seized the bullet with the fine long American forceps, but very firm traction made no impression. Having inserted the edge of my left index finger-nail between the outer edge of the bullet and the bone, I followed it with the point of a steel elevator, and prised the bullet out from what, as seen by these exact representations, was evidently the uneven bony bed in which the bullet had moulded itself.

The weight of the extracted bullet (126 grains) accurately corresponded with the weight of one of the bullets left in the revolver.

These figures show one of the bullets with, the other without, its metallic cartridge; all the illustrations being of natural size.

The extraction was effected without violence, once the elevator was placed under the foreign body and worked with my left hand, while the right index-finger acted as a fulcrum. Nothing was introduced into the ear, and little blood was lost. Free vent was afterwards allowed for discharge, which was collected in absorbent antiseptic pads, specially prepared by Messrs. Southall Brothers and Barclay. As the discharge was fetid, the pads acted agreeably as deodorisers, and their downy softness was so comfortable, that the patient's repeated wish was for more pads. At first ice was applied to the head by an ordinary ice-bag; but, as the temperature rose, a continuous current of iced water cooled the head through one of Galante's syphon tube caps, which, fortunately, Mr. Salt had just previously brought over from Paris. The effect of this appliance was very speedily to reduce the temperature two degrees; but though there was unremitting care under the immediate supervision of my house-surgeon, Mr. Westwood Moore, cerebral compression ended in death forty-two hours after the operation.

Birmingham.

A CASE OF STRANGULATED CONGENITAL HERNIA IN A CHILD FOURTEEN MONTHS OLD; OPERATION; RECOVERY.

By WILLIAM MONTAGUE BALL, M.B.

THE chief points of interest in this case consist in the early age of the patient and in the closure, after the operation, of the internal abdominal ring to a sufficient extent to prevent re-descent of the intestine.

On Feb. 22nd, at 8 P.M., the child, a fine little boy, fourteen months old, was brought to my house, very pale, and evidently in pain. The mother stated he had been ruptured since birth, but that, having been always able to "put it back," she had neglected the advice of procuring a truss; that morning, however, the bowel had come down during a fit of crying, and she had not been able to return it. She also said he had been sick several times.

Upon examination I found a swelling extending along the right inguinal canal into the scrotum, tense, tender, and with no impulse on crying. Having tried taxis for a reasonable time, both in and out of a warm bath, I left the child for the night, after giving it a small dose of opium, slung up in a kind of hammock, with its hips much elevated and an ice-bag on the tumour.

The next morning, at eight o'clock, still being unable to effect reduction, I asked my friend Dr. Sydney to administer chloroform, and finding the hernia still irreducible, proceeded to operate in the usual way, using Lister's steam-spray and his antiseptic precautions. On reaching the sac it was found distended with a small quantity of dark-coloured fluid; the intestine was a good deal congested and showed evidence of strangulation. The seat of stricture was at the internal abdominal ring. Owing to the child being very fat considerable difficulty was experienced in dividing the stricture to a sufficient extent to allow of the bowel being returned; eventually this was accomplished and the wound brought together with catgut sutures, and dressed antiseptically. The child was ordered to be fed on milk and lime-water, and half a drachm of tincture of catechu was administered. In spite of astringents the bowels acted copiously within twenty-four hours, and the child vomited once during the night. The dressings were removed in forty-eight hours, and the wound was found to be quite healthy and closed at the lower end. Temperature 100° 2' F.

Feb. 26th.—Patient passed a very restless night, moaning

and crying a great deal. Wound again dressed, the deeper portion connected with the abdominal cavity quite closed, the more superficial part, however, had gaped somewhat, owing doubtless to the difficulty of keeping so young a child from wriggling about, notwithstanding it was confined in a box-splint. The abdomen was very tympanitic and very tender. Temperature 103°; pulse 180. Bran poultices to be constantly applied and one grain of compound ipecacuanha powder with a quarter of a grain of calomel to be given every four hours. This treatment was carried on for some days, the opium keeping the child free from pain; and although but little hope was entertained of recovery, eventually the tympanites disappeared and tenderness over the abdomen ceased.

The wound on the fifth day was found to be suppurating freely, and so was dressed with carbolic oil in gauze. A sinus extending four inches in the direction of the right hypochondrium formed and had to be pressed out twice daily. After the first movement of the bowels, they acted once or twice daily during the progress of the case. The child was able to take the breast throughout its illness.

March 28th.—Wound quite healed and patient allowed to crawl about with a pad-and-spica bandage.

April 3rd.—A truss was applied and the child able to run about once more.

July 10th.—I saw the child running about, and the mother tells me it has been quite well ever since, and that there has been no appearance of any return of the rupture, although the truss has occasionally been left off for some time. I presume that during the attack of peritonitis which succeeded the operation, enough coagulable lymph was thrown out to procure a sufficient closure of the internal abdominal ring to prevent any re-descent of the bowel.

Hounslow.

GUNSHOT WOUND OF THE MEDIAN NERVE.

By EDWARD LAWRIE, M.B.,

PROFESSOR OF SURGERY, LAHORE MEDICAL SCHOOL.

IN the early part of May this year a boy named G. C.—, aged ten, was accidentally struck in the right arm by a charge of small shot. Several pellets were removed by his medical attendant from underneath the skin in the neighbourhood of the elbow, but none appeared to have penetrated more deeply. A good deal of superficial inflammation followed, and the boy lost the use of his forearm and hand. It is not clear from the account of the friends whether this paralysis was immediate or came on gradually. He suffered great and increasing pain in the arm and corresponding side of the neck and body, and was brought to me July 27th, 1880. I found a very peculiar drop of the right wrist and loss of power of the forearm, together with exalted sensibility in the palm of the hand. There was much glandular and lymphatic enlargement, which obscured the diagnosis, but thickening of the median nerve was satisfactorily made out about the middle of the arm, and I therefore cut down upon it. When exposed, the nerve was more than twice its proper size, and I was about to stretch it when I detected a hard body in its interior. Instead of stretching, a longitudinal incision was made into its substance and a pellet found and removed. As the operation was performed antiseptically, the wound healed by first intention; the boy rapidly recovered power in the forearm and normal sensation in the hand, and was discharged cured on August 6th, 1880.

Lahore.

THE PARKES MUSEUM OF HYGIENE.—This museum was reopened last Monday (after the usual vacation) in connexion with the introductory *conversazione* of the Medical School at University College. There was a good attendance of gentlemen and students, who manifested much interest in the collection of sanitary appliances, to which several additions have recently been made, including concrete and stoneware goods from the Poole pottery district. Messrs. Tonks and Son have added to their contribution a model of a new ventilator, called "the architrave ventilator," designed by Mr. Mark H. Judge, for the purpose of making an architectural feature of the provisions for ventilation. The Parkes Museum will continue to be open free on Tuesdays, Thursdays, and Saturdays.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum, et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. THOMAS'S HOSPITAL.

OMENTAL HERNIA; TWO OPERATIONS; RECOVERY.

(Under the care of Mr. MASON.)

The patient was about twenty-six years of age, and for two years previously had suffered from nausea and vomiting after taking solid food. In the right femoral region was a swelling of a doughy character, and somewhat painful to the touch. Eight months ago Mr. Mason operated and removed a piece of omentum about the size of a walnut, using the actual cautery. The antiseptic spray was not employed, and dry dressings only were applied. The temperature remained normal throughout, and an excellent result seemed imminent, but the sickness by degrees returned, due, doubtless, to the formation of fresh adhesions, and the operation was a failure. Six months later a second operation was performed under the antiseptic spray. A careful incision was made down to the sac, which was opened, and a further piece of omentum was removed. Catgut ligature was used. A gland was also taken away, and an attempt was made to effect a radical cure by transfixing the margin of Gimbernat's ligament and Poupart's ligament with a harelip pin, and drawing the edges together with a catgut ligature. There was no rise of temperature at any time after the operation. There was, however, for a time some tenderness in the femoral region. In the meanwhile the patient was relieved from the distressing vomiting after meals, and it was hoped that the relief would be permanent.

Remarks.—Amongst the points of interest associated with the case is the fact that two operations were performed on this patient, one in which the antiseptic spray was not used, and the other in which antiseptic precautions were strictly carried out. In both instances there was no rise in temperature, suggesting that in some cases at least an equally satisfactory result obtains whether the so-called antiseptic or the more simple method of dressing is employed. In several other cases done without "strict" antiseptic precautions, union took place as nearly as possible by first intention, even when the sac had been opened.

METROPOLITAN FREE HOSPITAL.

A PIECE OF BREAD IN THE LARYNX; IMMINENT ASPHYXIA; TRACHEOTOMY; RECOVERY.

For the notes of this case we are indebted to Mr. H. T. Groom, M.R.C.S., house-surgeon.

John K—, aged two, was admitted on August 5th last, to all appearances dead. The mother, who was in great distress, hurriedly explained that the child had been eating some bread a minute or so before, and that a piece suddenly went "the wrong way." The little patient's face and lips were of a bluish tinge. Neither pulse nor heart could be felt, nor could the latter be heard with the stethoscope, and breathing had actually ceased. On making an attempt at artificial respiration, however, a spasmodic movement of the diaphragm took place, but no air entered the lungs. There were a few bread-crumbs in the mouth, and these were cleared away. Nothing else could be seen or felt, and it was deemed useless to waste time in the endeavour to take anything away from the larynx. Accordingly, tracheotomy was at once performed by Dr. Byrne, by means of the trocar and cannula made for that purpose. The trocar was withdrawn and the result anxiously awaited. Artificial respiration was kept up, and in about twenty seconds the first voluntary inspiration took place. In a few seconds more there was a stronger one, and again two or three more, when the child gave a cough, and out from his mouth "popped" a piece of bread about three-quarters of an inch in diameter. Gradually the child improved, and coughed some more crumbs

through the tube. The mouth of the tube was then closed up; and it being found that the child breathed quite naturally it was withdrawn, and a piece of wadding was placed over the wound. The child was then taken up to the ward, but in a few minutes was found in a state of collapse, and breathing very faintly. Brandy and water was administered and slowly he revived. There was a great deal of rattling in the throat; and as bread-crumbs constantly were exuding from the wound, an emetic of sulphate of zinc was given, in the hope of bringing them away. Vomiting shortly took place, but with the exception of a quantity of frothy mucus, nothing of any consequence came away. The boy shortly after fell into a heavy sleep, which lasted for some hours, and on waking drank freely of some milk. From this time forward he progressed quite favourably towards convalescence; the wound healed rapidly, and only a slight attack of bronchitis occurred, which yielded to the usual remedies. He was discharged cured on August 21st.

SOUTH STAFFORDSHIRE HOSPITAL.

A CASE OF DISLOCATION OF THE FOOT BACKWARDS FROM A BICYCLE ACCIDENT; REDUCTION; RECOVERY.

(Under the care of Mr. NEWNHAM.)

For the notes of this rare and interesting case we are indebted to Mr. W. H. T. Winter.

Chas. R—, aged nineteen, was riding a bicycle on July 10th when the machine turned over. In jumping off to save himself he caught his foot between the treadle and the crank. He felt a wrench, there was great pain, and he was unable to walk.

On admission into the hospital it was found that the foot was dislocated. In the injured limb, as compared with the sound one, the malleoli were farther apart than natural. The anterior margins of the lower ends of the tibia and fibula were distinctly made out, and there was a hollow beneath them over which the extensor tendons of the toes were stretched. There was no fracture of either the tibia or the fibula. The long axis of the foot was apparently shortened and turned a good deal outwards. The sole looked downwards, outwards, and backwards. The astragalus could not be distinctly made out. The heel was abnormally prominent, and there was a considerable hollow between the tendo Achillis and the tibia. The sustentaculum tali was farther backwards than it should have been. Voluntary motion of the foot was completely abolished and passive motion was almost impossible.

The patient was put under ether, and the dislocation reduced by flexing the foot and rotating inwards, rotation outwards having failed.

Some swelling followed, and was treated with cold lotions. The boy could walk well in seventeen days, and put the ankle-joint through all its movements.

SALFORD ROYAL HOSPITAL.

TWO CASES OF FRACTURE OF THE BASE OF THE SKULL IN CHILDREN AGED SIX YEARS.

(Under the care of Mr. WALMSLEY.)

FRACTURE of the base of the skull at such an early age as six years is a rare occurrence. In the second case there was paralysis of the facial muscles of the left side.

For the following notes we are indebted to Mr. D. T. Evans, house-surgeon.

CASE 1.—Thomas T— was admitted into the hospital on the 5th of July last, having fallen downstairs a distance of about 8 ft. He was somewhat unconscious when seen, and there was copious bleeding from the right ear, followed on the following day by the discharge of sero-sanguineous fluid in large quantities.

On the 7th bilateral convulsions appeared, recurring at intervals during the day, and on the 8th the discharge from the ear was more profuse, the convulsions appeared more frequently, and about mid-day he died. The post-mortem examination revealed, in addition to a fracture across the middle fossa of the base of the skull, and of the petrous portion of the temporal bone, a fissured fracture of the frontal bone, extending to the coronal suture on each side. In addition there was a large clot of blood effused between the bone and the dura mater at this point.

CASE 2.—James G.—was admitted on the same day as the previous case—namely, July 5th—in an unconscious condition, having fallen off a swing. There was free and copious bleeding from the left ear, with paralysis of the facial muscles on the same side. On the following day the child had recovered consciousness, but remained somewhat stupid for some days longer. The serous discharge from the ear, which had been very profuse, ceased on the 7th; and on the 11th of July—the sixth day after admission,—the child was bright and sharp. He left the hospital on the 10th of August perfectly well, the facial paralysis, however, still remaining. It may be noted that the hearing on the left side was not affected by the injury.

ABSTRACTS OF INTRODUCTORY ADDRESSES.

ST. THOMAS'S HOSPITAL.

INTRODUCTORY ADDRESS BY DR. ORD,
PHYSICIAN AND LECTURER ON MEDICINE TO THE HOSPITAL.

THE address was devoted to the subject of Medical Education, chiefly from the point of view of the parent and the student, partly from the point of view of the Medical School. Beginning with the question as to whether boys who were intended for the medical profession should pursue any special course of education while at school, the lecturer answered this question most decidedly in the negative. The use of a school education was to fit men for the general purposes of life, to train them to take their place in society. To this end boys should be brought up in large schools, with a healthy public opinion, in which by their reaction on one another they tended to acquire moral symmetry. Their studies should include the classics, as well as modern languages, history, geography, mathematics, and natural philosophy. After a few words in defence of the Classics, the lecturer proceeded to indicate the position to be occupied by natural sciences in the teaching of the boys. "Of two things I am certain—that they ought to form a part of the school schedule, and that they ought to be taught without reference to the special use of any one of them in the particular direction of the path which the boy is to follow in his later life. They should be taught, on the contrary, for their general usefulness, so far and in such a way that the man may be able to apply them in the many conjunctions of life in which a knowledge of them can be helpful. So, for instance, that the man may be able to read his barometer or thermometer, may be able to judge of the quality of his instruments, may be able to see that they are in proper working order; that, for another instance, he may be able to avoid grave physiological errors in the management of his own health, in the sanitary regulation of his house and household, matters requiring elementary knowledge of chemistry, physiology, and physics, and not a little that he may be able, during the intervals of his statutory labours, to enjoy in an intelligent way the manifold varieties of natural objects. To secure such kind of knowledge in this department, it is imperative that the teaching be practical and that the boy make many of his own experiments. Teaching by books and diagrams only is as absurd a waste of time as it would be to try and make a boy read Virgil properly by giving him a grammar and a dictionary. The phenomena must be seen, the apparatus handled. Let the boy make his own oxygen, learn to use his pneumatic trough, see the effects of rubbing his stick of sealing-wax with his silk necktie, dissect for himself the heart or eye of a sheep—all, of course, under skilled inspection;—let him then be helped to reason on the causes or laws of what he has seen. Only in this way can the interest, without which no study can be healthily pursued, be excited. Who among us does not remember the infinite weariness and distaste inspired by the diagrams of his first botanical lecture? Yet many of us may have seen boys and children charmed by a talk over a few flowers gathered in a country walk and pulled to pieces at some resting-place; may have seen their curiosity awakened, their interest attracted, as the parts of the flower were indicated and their uses explained; and may have watched these children go on to search for more flowers and to observe for themselves, or return with eager questionings. There is much truth in

these words of Goldsmith:—'Might natural philosophy be made their pastime in school, by this means it would in college become their amusement. At first it would be sufficient if the instruments and the effects of their combination were only shown; the causes should be deferred to a maturer age, or to those times when natural curiosity prompts us to discover the wonders of nature.'

"There is one use of the studies of observation which offers opportunities at present, in my opinion much neglected, of establishing a sort of co-operation between them and the study of language. There was, when I was at school, a practice still existing, and much countenanced by the authority of tradition, of making boys write essays and verses by way of exercising them in composition. From my school days upward I have judged this practice to be both imperfect and fallacious. It has been condemned by Milton in such terms as these: 'A preposterous exaction, forcing the empty wits of children to compose themes, verses, and orations, which are the acts of ripest judgment, and the final work of a head filled by long reading and observation with elegant maxims and copious invention.' He might have added, that they are a premium and incentive to imposture and plagiarism in the many, while they thus distinctly foster abnormal development in the few. If we remember, as I believe all must admit, that description must follow and complete observation, we shall see that we have in these studies a valuable means of training boys in accuracy of language and simplicity of composition. Let boys be made to describe, in the fittest and fewest words, the natural processes or objects which they have been observing. Instead, then, of regarding what are called synonymous words as words having the same meaning and to be used, as the poets use them, according to the convenience of sound or rhythm, they will learn to attach to each word its own true meaning, and will come to see that for their word-painting they have a dozen various shades or tints where their gradus would tend to make them believe they had but one. I would rather have a boy write such descriptions of a mineral, a plant, or a phenomenon as would give his reader a clear idea of it, than the most eloquent essay on the Beautiful or the most polished set of verses.

"His school career finished, the prospective student should not at once proceed to a hospital, but spend some months in preparatory training. There are grave moral objections to the plunge from the restraint and supervision of school life to the almost unrestricted freedom of a hospital. And there are great advantages in giving him now preliminary instruction in some of the elements of medical practice, and in science related thereto. A revival in modified form of the old system of apprenticeship is advocated. The course to be taken by the student will vary according as—(1) he proposes to go to Oxford or Cambridge for his degree; (2) to the University of London, in which case it is most desirable that he pass the Preliminary Scientific Examination before entering the hospital; and (3) if he propose to take only the diplomas of the London or other colleges. In any case he should spend some time in a good chemical laboratory, and some time in learning practical pharmacy and dispensing, the latter either with a good general practitioner, or in a provincial hospital or infirmary.

"In relation to proper hospital study the extent to which it is desirable that the London medical schools should teach the sciences preliminary to medicine requires discussion. It is probable that though this work is fairly well done, it would be better done if some common college were established in which these subjects might be taught, as at Edinburgh, to large classes, the hospital schools restricting their teaching to pure Medicine and Surgery, with perhaps Anatomy and Physiology.

"As regards study in the wards and out-patient rooms, this must not commence until anatomy and physiology are fully mastered. In the beginning, and throughout this final study, the student must bear in mind the necessity of making himself practically acquainted with, and skilled in the use of, all means and instruments of investigation. These increase yearly in number and perfection, the scientific toys of one generation becoming the indispensable armament of the next. With their aid he will test and analyse the group of many symptoms presented by each case, leaving, so far as he can know or suspect, no single symptom or possible condition unregarded. And then will come the use of his higher analytical power and judgment to give each symptom its due weight and real meaning, rejecting one by one the possibilities which may be indicated by separate symptoms

but are excluded by the whole group, until he has come to his diagnosis. In treatment, as well as in diagnosis, he will need a large amount of instruments and drugs. According as his diagnosis shall have been accurate and profound, so will his treatment be rationally directed in the main to the removal of the ultimate causes of each disease. All this he will begin to learn when he enters the wards. If he be true to himself, he will be still learning this when he is old."

QUEEN'S COLLEGE, BIRMINGHAM.

INTRODUCTORY ADDRESS BY MR. BARTLEET,
PROFESSOR OF PHYSIOLOGY IN THE COLLEGE.

THE winter term of Queen's College, Birmingham, was commenced on the 4th inst, by the usual inaugural address and the distribution of prizes, the address being delivered by Professor Bartleet.

Professor BARTLEET, in the course of his address, referred to the address delivered by Professor Huxley at the opening of the Mason College, and said that they who were so deeply interested in practical science would heartily welcome any new organisation for scientific teaching, and desire that no rivalry should exist between the two great institutions, save that of which could do the most good. After Professor Huxley's profound, scholarly, and eloquent address, he might well be allowed to pass by the time-worn, though still important subjects of education, of medical politics, or economics, and address himself, as he felt duly bound, to his fellow-students of Queen's College, old and young; those *in statu pupillari*, and those who had graduated, not only in medicine, but in age and honours. Some of them would be springing at a bound from the position of pupilage to the greater freedom of college life; some might be closing that day the wholesome restraint of home ties. The very fact of tying themselves down to a special life work should induce serious thoughts—thoughts more serious when it entailed the responsibility of the life and death of others. He purposed briefly to show what they must expect and what they must not expect from the profession. They certainly must not expect wealth. To accumulate riches was not the lot of many in the medical profession. The prizes were few and of moderate value. A moderate competence might be obtained by a man who practised his profession competently, reputably, and honourably. Nor must they expect to gain honours by those social positions and dignities usually attractive to men—the bench, the mayoralty, association with the party in power, and real or unreal dignities of all kinds. In a busy manufacturing and commercial district wealth and distinction usually went together, and here, in addition, politics and position were inseparable. Members of the medical profession were usually not wealthy, and commonly had but little time to devote to work outside the profession—indeed, they had so much unpaid work to do that they rarely were, at all events, allowed any of the distinctions which were the legitimate and commendable aim of good citizens. To some extent they were valued by others at the rate at which they valued themselves, and it would add to the dignity of the profession if their services were gratuitous to those who could not afford to pay, and they charged those who were at a rate proportionate to their means. Many members of the profession felt acutely the scant recognition gratuitous services received at the hands of the public. They felt acutely, sometimes bitterly, the apparently studied indifference to their claims, and the hardship of its members being rarely recognised as doing a public work. It was often alleged that the physicians and surgeons of the hospitals and the professors of medical schools gained direct advantages from their official positions, and that such posts were coveted and assiduously sought for if vacant. Allowing that to be true, and as far as direct gain was concerned it was far less than was supposed, did they not sometimes see competition for a seat in the town council or on the board of guardians, or even in the Imperial Parliament? At least they did before a paternal caucus settled all those matters comfortably for them. Did the gentlemen who filled these useful, important, and honourable posts so ably perform their duties solely from love for their fellow citizens? Did none of them enjoy the work itself or appreciate the prestige attaching to official positions? Did none of them look forward with laudable ambition to the well-deserved honours that fell to the lot of men who, at some sacrifice,

had undertaken public work? His jeremiad might be summed up in a single sentence: "In Birmingham no work is considered public work that is not at once municipal and political." But even this dark side had a silver lining. If they did not realise a fortune they might gain a competence, and that without some of the anxieties and responsibilities attached to commerce. If they did not gain the applause of the many they could gain the love of the few. If they did not gain high places amongst men they would, if they deserved it, gain that which such dignities did not always bring—the verdict of a self-approving conscience; the knowledge that by God's help and God's providence, the breadwinner had been given back to a desolate family, the wife restored to a heart-broken husband, the infant had had the blessings of a mother, and the fondly-loved child had been renovated in health and strength. Was not that better than wealth, better than a life of ease, better than transient honours and dignities? And there was something else they would gain—they would gain an entrance into the medical brotherhood—no slight gain when they considered the fidelity and self-sacrificing affection to one another. Alluding to the different branches of the profession, he pointed out that the widespread desire for extending higher education and the growing importance attached to scientific studies would afford a larger occupation to teachers of science. Speaking of the practising part of the profession, he pointed out the advantages of the general practitioner over the specialist, and cautioned them against thinking they were too good to be general practitioners. The general practitioner was the backbone of the profession, the man prepared to cope with difficulties of every kind in every department of general and special practice, honoured in his district as those in special practice rarely were. In conclusion he gave some good advice to the students as to their studies, urging them to work.

LEEDS SCHOOL OF MEDICINE.

INTRODUCTORY ADDRESS BY MR. CHAS. J. WRIGHT,
LECTURER ON PHYSIOLOGY, AND SENIOR SURGEON TO THE LEEDS
PUBLIC DISPENSARY.

THE lecturer said the preliminary examination which medical students had to undergo was a fair test of the general education which was an essential for every man who aspired to a position in an honourable profession; but he trusted the day was not far distant when other subjects, in addition to those now demanded, would be relegated to preliminary studies, instead of, as at present, being left to overcrowd the but too limited time at the disposal after the curriculum was commenced. Such subjects, for instance, as experimental physics, biology, botany, and inorganic chemistry—the last-named even now often included in the subjects of preliminary examination, and thus excused after registration—all useful as a mental discipline, most invaluable as an aid to future study, but liable to interfere with due attention to other subjects after medical studies begin.

"And this not merely as a discipline. To tell or show a man a thing is 'not to teach him to observe, but to make him a mere recipient of another's observations,' and we are perhaps at times rather apt to forget this fact in our teaching. But, it may be said, may not some of these studies in physical science be carried on during a twelvemonths' pupilage with a practitioner, or at some small provincial hospital, prior to entering at a medical school, thus combining a training in natural science with an insight into the routine of prescribing and the art of compounding drugs? Many of the examining boards permit one of the four years enjoined as the minimum for medical study to be spent in this manner, allowing for not more than twelve months from the date of registration. This is a modification of the old system of apprenticeship, long since abolished as a necessity; which, although it may in some cases have had its advantages, was an arrangement in which these were more than counterbalanced by its evils. Opinions in the present day are divided as to whether a certain period (twelve months) should be spent—say in the surgery—in this manner before attending lectures. Where a man is young, and has the good fortune to reside with one who has the time, ability, and inclination to aid his pupil, it is possible that much information as to the management of patients, and of a practice generally, may be acquired, and time be profitably spent in gaining a fair knowledge of 'Osteology,' which is always of the greatest use before commencing to dissect, or to attend

lectures on anatomy. But experience leads to the conclusion that, if a tyro has the choice—it is better not to commence lectures too early, but to do so as soon as the elementary studies (and examinations) are disposed of, and to leave the residence with a practitioner until at least the 'Primary' Examination (in Anatomy and Physiology) are passed. After that he will devote his whole energies to his hospital work, and may, when opportunity offers, most usefully combine therewith the duties of an assistant to some surgeon, who can allow a certain time for the school and hospital. The suggestion that at least two years should elapse between the passing of the 'Primary' and Final Examination, which has been already acted upon as a stipulation for the Licence of the London College of Physicians, is, I think, an admirable one, and one which favours the view I have advanced.

"Then, gentlemen, you will find, when once launched upon your career, that examinations are very numerous. A recent proposal of the Royal College of Surgeons (which, however, has been for the present abandoned) to institute an examination in anatomy at the end of the first year, in addition to the usual one after the second winter session, originated no doubt in a plausible motive—viz., that of being an incentive to good steady work during the first winter session specially, which is not always, unfortunately, utilised to its fullest extent. It would, however, had it been established, have added unnecessarily, and to my mind without corresponding gain, to the burdens of more especially the provincial students, unless indeed it could be held at each individual school." Touching upon the subjects which the students would have to master, he urged them not to neglect that department of anatomy which was too apt to be overlooked—the contemplation of the prominencies and outline of the body and limbs in a normal condition, and the changes which they underwent in movement, with the relation of arteries and viscera to the surface, so that in examination and operation they might know where to look for them. He also suggested the cultivation of the habit of making themselves familiar with the normal before proceeding to the study of the abnormal conditions, not only with regard to limbs and viscera, but in commencing the use of the various aids to diagnosis which were now so complete and numerous. With regard to physiology, he observed that though it had made vast strides of late, there were still connected with it very much of what had been denominated "unknown territory." After expressing his regret at the restrictions imposed upon physiological researches by the Vivisection Act, and alluding to some of the advantages which had resulted from experiments on living animals, Mr. Wright traced the history of the Leeds School of Medicine, and concluded as follows:—The increasing requirements of examining boards had resulted in the gradual widening of the subjects to be taught, and that had recently been aided by the development of colleges of arts and sciences in our large towns, and especially in those where provincial schools of medicine had for years existed, and by the extension, by scholarships and endowments, of the facilities for placing a sound literary and scientific education within the reach of many who had hitherto failed to acquire it. Of the seven provincial schools in this country, four were already incorporated with colleges of that kind, and the large centres of population in which the other three were situated each possessed one in a more or less complete stage of development. The Manchester Royal School of Medicine had for some time been incorporated with Owens College, and but a few months ago they had witnessed the foundation by Royal Charter of the more stately Victoria University, having its seat in the city of Manchester, and which, though it had not obtained the power to grant medical degrees, now commenced its foundation with every prospect of a glorious future. They might, he trusted, look forward to the not very distant date when their own Yorkshire College might be enabled to comply with the terms of affiliation, and thus be constituted a college of that University. Might he venture to express a hope that the date was not distant when some closer union might be effected between the Yorkshire College and their own School of Medicine? It was impossible to contemplate either the present or the future of their school, or to reflect upon possible changes in their administration, without a pang of remorse at the very great loss they had this year sustained in the death of one who freely gave so much of his time, means, and energies in his devotion to the interests of all the three institutions he had named. So far as the Yorkshire College was concerned, it was not too much to say

that it was to a large extent due to John Deakin Heaton (as its chairman of council) that many of the early obstacles to its formation were surmounted; while as regarded the Infirmary and School of Medicine, his long service of conscientious and disinterested labours, extending, as regarded that school, over thirty-seven years, were so fresh in the minds of all who knew him, that they needed no words of his.

At the conclusion of the address, prizes were awarded as follows to the students:—

Winter Session, 1879-80.—Anatomy (Junior): Certificates, H. J. Robson and T. J. Walker. Anatomy (Senior): Medal, John Dacre; certificate, W. J. Waddington. Physiology: Medal, J. Dacre; certificates, Arthur Bowe and A. A. Ward. Lecturer's Prize: J. Dacre. Practical Physiology and Histology: Medal, J. Dacre; for summer examination, 1879, March, certificate, J. H. Naylor. Chemistry: Medal, H. Child; certificate, H. J. Robson. Surgery: Medal, J. W. Deardon; certificate, F. H. Mayo.

Summer Session, 1880.—Botany: Medal, G. I. Wells; certificate, H. Child. Materia Medica: Medal, Robert Smailes; certificate, J. H. Naylor. Practical Chemistry: Medal, Herbert Child; certificates, J. J. Mountain and J. N. Hawkin. Midwifery: Medal, John Dacre; certificate, A. A. Ward. Practical Physiology and Histology, &c.: Medal, Herbert John Robson; certificate, J. N. Hawkin. Pathology: Prize book and certificate, F. H. Mayo. Forensic Medicine: Medal, J. W. H. Brown; certificate, Frederick Wilson.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.

INTRODUCTORY ADDRESS BY DR. WATERS,
LECTURER ON MEDICINE.

AFTER a reference to the advantages to medical students offered by the Liverpool Royal Infirmary, and the proposed establishment in the city of a college for higher education, to be called "University College," the lecturer proceeded to set forth the difficulties which would be encountered by those entering upon the study of medicine. He then spoke of the relative importance of the different subjects of the curriculum:—"Amongst the most important of these, anatomy stands out prominently. It may be safely said that no man can become a sound or successful physician or surgeon without a knowledge of this science. It lies at the root of all your studies, and you will find in this school the amplest means and opportunities for acquiring a practical knowledge of it. The science of anatomy, in the ordinary sense of the term, may be said to be perfect. It is true that with regard to minute investigation much may remain to be discovered, but in reference to ordinary anatomy our knowledge is complete. You will find the study of it not only essential to you in order that you may pass your examinations, not only in reference to the study of disease and accidents, but also of the highest value as a training for the mind, and of the greatest importance to you in any original inquiries in which, as physicians or surgeons, you may hereafter engage. Physiology is another subject of special interest and importance to you. Unlike anatomy, it is an imperfect science. Still, much is known of the functions of the animal economy, and every year is rendering our knowledge more complete and precise. The study of physiology possesses a fascination which few other studies possess. It is daily becoming more generally taught in our schools, and the knowledge of it is, therefore, becoming more diffused. It is looked upon now as almost a necessary part of the education of both sexes. I consider this introduction of the study of physiology into our schools as of the highest importance. As a training for the mind it is of great value, but as inculcating a knowledge of facts which have the most direct bearing on the well-being of society it cannot be too highly esteemed. To you as practitioners of medicine it is essential, for if you would wish to estimate the amount of derangement which disease produces you must know how far that derangement is a departure from the normal state. A knowledge of chemistry will aid you greatly in your study of physiology. It will help you to understand many of the phenomena of organic life, and will often guide you in the treatment of disease.....It is in the wards of your hospitals,

at the bedside of the patients, that you can alone learn to recognise and treat disease; and there is too great a tendency on the part of students to neglect the clinical part of their work, and especially in the early days of their attendance at their hospitals. Those who are unacquainted with the difficulties which beset the progress of medicine are apt to imagine that the advances made in it are not commensurate with those which are made in other sciences. Now let us for a moment consider this point, for I am one of those who believe that, in proportion to the difficulties which surround the investigations of medicine, the discoveries in medical science and the advances in medical art have been as great as those which have marked the history of any other science or art. I should wish to be in no wise misunderstood. I do not for a moment under-estimate the difficulties which attend the investigations of the physical philosopher, and I admit most willingly, for instance, that the precision which characterises the labours of the chemist, and the exactitude with which the predictions of the astronomer are fulfilled, demonstrate the high degree of perfection to which their respective sciences have been brought. But the subjects to which medicine relates immeasurably transcend those of the physical philosopher. The investigation of the phenomena of life is surrounded by difficulties such as the physicist never meets with. The unchangeable nature of inorganic matter gives rise to one unvarying result whenever inorganic matter is acted upon by the same cause. But organic matter is ever varying, ever unstable, and in that highly complex body which is the subject of the physician's operations there are so many circumstances beyond the mere physical, so many varieties of individual constitution, so many peculiarities, so many influences of a mental or a moral nature, that it becomes a problem, very different from that which the chemist or the astronomer is called upon to decide, when the physician has to consider the effects which the same cause will produce on different persons, or on the same person at different times. Were the science of life as perfect as that of chemistry, were we even thoroughly acquainted with the laws which regulate diseased action, there would still remain great difficulties in the treatment of disease. We should still have to study the peculiarities of each individual and carefully select the remedies appropriate to the case, and herein lies the great difficulty of therapeutics, but herein also lies its point of greatest interest. It is this which gives its great peculiarity to medicine—the ever-varying condition of those who are subjects of the physician's care; the manifold phases which the same disease presents in different persons; and, lastly, but by no means least, the different effects which the same remedy may produce in different individuals and in the same individual at different times. And in judging of the progress of medicine, these are circumstances which should always be taken into consideration. Some of the best original work ever done has been done under circumstances apparently the most unfavourable; and, therefore, let no man imagine that, although located far from the busy centres of intellectual or practical life, he may not, whatever be his calling, and especially if it be medicine, contribute something to the stock of human knowledge. *Non nobis solum nati sumus.*"

The prizes to the successful students of the winter and summer sessions were then distributed as follows:—

Lyon Jones Scholarships.—Mr. F. C. Larkin, Mr. J. W. Ellis, Mr. A. Barron, Mr. A. H. Wilson.

Winter Session.—Third-year subjects (Medicine, Surgery, and Pathology): Mr. R. Honeyburne, silver medal; Mr. F. J. Laimbeer, bronze medal. Second-year subjects (Advanced Anatomy and Physiology): Mr. A. H. Wilson, Terr gold medal; Mr. W. C. Garman and Mr. T. P. Lowe, bronze medals; Mr. G. Jones, first hon. certificate; Mr. J. R. L. Dixon, second hon. certificate. First-year subjects (Elementary Anatomy and Physiology and Chemistry): Mr. W. O. Travis, Bligh gold medal; Mr. Joseph Walker, bronze medal; Mr. F. C. Larkin, first hon. certificate; Mr. H. A. Bredin, second hon. certificate. Histological Prizes: Mr. A. H. Wilson and Mr. A. H. Clemow.

Summer Session.—Senior subjects (Medical Jurisprudence and Obstetrics): Mr. J. W. Ellis, bronze medal; Mr. R. Williams, hon. certificate. Junior subjects (Botany, Materia Medica, and Practical Chemistry): Mr. Joseph Walker, silver medal. Comparative Anatomy prize: Mr. F. H. Barendt. Extra prizes in Obstetrics: Mr. J. W. Ellis, first prize; Mr. R. Bredin, second prize. Students' Debating Society's prizes: First essay, Mr. W. C. Garman; second

essay, Mr. J. R. L. Dixon. Debating prizes: 1. Mr. Nevins; 2. Mr. J. G. Brown. Reports of Medical Cases, Mr. Laimbeer; Reports of Surgical Cases, Mr. Ellis. Prize for Specimens, Mr. A. Barron.

SHEFFIELD SCHOOL OF MEDICINE.

INTRODUCTORY ADDRESS BY DR. C. NELSON GWYNNE,
LECTURER ON PRACTICAL PHYSIOLOGY AND HISTOLOGY, SHEFFIELD
SCHOOL OF MEDICINE.

DR. GWYNNE began his address by an urgent appeal to the students to commence earnest work immediately, and not put it off till the second or third year of their studies. He drew attention to the special advantages afforded by the Sheffield School of Medicine. He then spoke of the latitude and grandeur of the science of medicine, and gave examples of its intimate relationship with the Physical Sciences, with Psychology, and the Arts. He next devoted a portion of his address to giving advice to the students as to the method of conducting their studies. He specially recommended the study of Physiology, and gave a short historical account of the advances made in that department since the discovery of achromatism. He went on to say:—

"When you have completed your second year of study, your chief attention ought to be directed to your hospital work. Let your attendance be regular, and never omit to take copious notes of the cases you have selected for your special attention. Don't endeavour to cope with a large number of cases at once, but, while giving a general attention to the clinical remarks made beside the bedside of every patient, choose out two or three medical, and as many surgical cases, for your special observation. Now is the time to acquire accuracy and method in the examination of your cases. Never yield to the temptation of making a quick diagnosis, based on some suggestive symptom, and jumping at a conclusion without having first gone through every step that leads up to it. First acquaint yourself with the previous history of your patient, and to gain this, let your questions be short, pithy, and to the point. Avoid all discursive conversation and unnecessary details. Next examine his general present condition, and let the skin, the digestive system, the urine, the circulatory system, the respiratory organs, the temperature, &c., all receive the attention they in each instance deserve. When you have gone through this general examination, the *locus* of disease will be pretty sure to suggest itself, and will demand further special investigation. Once acquire a certain method in examining your cases, and you will soon find yourselves in every instance intuitively, and with rapidity, following out the same method, and the result will be accuracy in your diagnosis and that confidence in yourselves, which is almost indispensable to the successful physician.

"Many of you may hereafter be called upon to carry out the duties of the 'Public Health Act,' and you will find them, in any case, multifarious and difficult; but a little time bestowed upon the subject now will enable you with much greater ease to accommodate yourselves to the duties that devolve upon you. There is little doubt but that all the licensing bodies ought to make the subject an integral part of their regular curriculum.

"After the student has entered on his second year, the question of paramount interest to him is the *choice of a diploma*. In regard to this you are in a certain sense unfortunate. You are commencing your professional studies in a transition period. We have not yet been divorced from the imperfect system of the present, nor yet wedded to the new system of the future. It is still reserved for only a comparatively small number to proceed to a respectable English medical degree. It is still competent for you to settle down and practise both in medicine and surgery, on attaining to the membership of the English College of Surgeons, if you elect to be satisfied with it. It is next door to impossible for you to acquire an English medical degree, except the few of you who have the pluck and energy to aspire to the degree of what is called the 'London University'—a university in nothing but in name—a sterile *alma mater* which adopts the children she never nurtured, without a staff of paid professors, without laboratories, without, in fact, any of the paraphernalia requisite for imparting knowledge or for adding to the aggregate of scientific discoveries. And when I say this, I am aware that the high standard required for its degrees has had a healthy influence on medical education

throughout the country; I am aware, too, that many of those who hold the degree of the London University hold a foremost position in the scientific world, and that others are progressing towards the attainment of that position; but, beyond stimulating their energies and testing their capacities, what has the London University done for them? It manifestly fails in the most valuable duty of a university—viz., in teaching.

"The possession of a certain amount of knowledge in a student is not the main desideratum; it is more important to form his habit of mind and to direct his method of investigation. The student who has attained to his degree after a four years' period of study is, however he may estimate himself, but a child in knowledge, and being but a child, the fashioning of his mind for a progressive life-long student-ship, the laying down a sound groundwork for future labours, is vastly more important than to foster precocity, and, in many instances, after-idleness, by cramming his brain with numberless facts and a variety of details. We hear far too much at the present day of examining boards, and far too little of university teaching. In these remarks I do not include Scotland and Ireland, for I am well aware that the Universities of Edinburgh and Dublin have never neglected the duties they owed to medical education. But in England, unfortunately, owing to a variety of causes, it has been different, and it is only lately that, with an energy that deserves all praise, the University of Cambridge has determined to revive the teaching of medicine in its walls, and to roll away the reproach that so long attached to it, of snubbing and neglecting a study that directs to the alleviation of human suffering the most universal scientific investigations. The exertions of the University of Cambridge in the south we are soon likely to see emulated in the north. The want of a university for the north has at length been recognised, and the Victoria University has received its charter and entered upon its mission—a university in deed as well as in name, with splendid lecture halls, museums, and laboratories; with a staff of paid professors, and every requisite necessary for the acquisition of new knowledge; with colleges to be affiliated with it in each of the large neighbouring towns, our own included. Untrammelled by an ancient history, or by old associations with pedantry and prejudice, it starts buoyant with health and hope, soon, if I mistake not, to lead the van, and leave behind in the race older but more lagging competitors.

"We have waited too long in the hope that successive governments would legislate for us, and put medical education in this country on a better and more uniform footing. 'The gods help those who help themselves.' It is time that we set to work and bring about our own reformation. It will be a long time before we have in this country an equivalent to the German 'Staats Examen.' With the Government imposing implicit confidence in the General Medical Council, and with the well-known proclivities of that Council, we may fairly predict that we will not in this generation witness much advance towards such a denouement. Perhaps if we were fortunate enough to be under a system of government that fostered science things might be different; but unfortunately the sciences and arts in this country alone, of all great nations, are left to struggle as best they may for existence, and are destined to receive official snubs much oftener than the assisting hand. I need not remind you of the army and naval medical services, which are, thanks to the persistent efforts of the profession, ably backed up by the medical journals, only just emerging from behind the cloud of disfavour under which official mismanagement has placed them. Since, then, we may have to wait a long time for the establishment of a one-portal system, it is manifestly our duty to make the best of things as they exist. If among all the different corporations that granted medical and surgical diplomas there existed a healthy rivalry; and if their aim was in each instance efficient teaching, and to make a high standard of acquirements necessary for attaining to their diplomas, rather than merely to secure a preponderance in numbers; if, I say, such a state of things could be brought about, and there are not wanting signs of it already, it would be quite unnecessary to agitate for a one-portal system. There is no doubt but that, in any case, certain changes would have to be made. Among them, I would mention the making of it obligatory on the general practitioner to acquire a medical as well as a surgical diploma. Again, the establishment of a uniform standard for the preliminary examination would be most desirable, and the entrusting the conduct

of the examination to bodies in no way connected with the licensing bodies. It would also be very desirable, and a great boon to the students, to institute a preliminary scientific examination, which would include such subjects as botany, zoology, and chemistry, and thus lighten the already over-crowded curriculum. With the many advantages connected with the one-portal system, however, there is combined also a grave disadvantage; that is, that the great majority of general practitioners would be quite content to practise on the licence conferred on passing the 'Staats Examen,' and would not care to go to the additional expense and labour to obtain a degree from one of the universities or the old corporations. Such a result would naturally react upon these bodies and tend gradually to diminish their popularity and enfeeble their energies.

THE ARMY MEDICAL SCHOOL AT NETLEY.

THE winter session of the Army Medical School was opened at Netley on Monday, the 4th inst. An unusually large number of surgeon-probationers were present—viz., sixty-nine for the Army Medical Department, twenty-six for the Indian Service, and five for the Royal Navy, making an exact total of one hundred. The introductory discourse was delivered by Professor Longmore, C.B., his subject being principally a discussion of the question of applying the antiseptic method to the treatment of wounds in military practice in the field. In the course of some preliminary remarks the lecturer adverted to the fact of the Army Medical School having been opened by Lord Herbert at Fort Pitt, Chatham, in October, 1860, so that twenty years had now passed since that event took place; and he mentioned that during these twenty years as many as 1588 surgeons had passed through the School prior to receiving commissions in one or other of the branches of the public service. Of this number 804 had entered the Army Medical Department, 568 the Indian Medical Service, and 216 that of the Royal Navy. The following statistics regarding the surgeons who had joined the Army Medical Service were of interest:—Out of 804 surgeons there remained at the present time 583 in active employment—thus showing a loss by casualties of different kinds during the twenty years amounting to 221, or something over 27 per cent. These 221 casualties were made up of 115 surgeons lost by death, 76 who had left the service for various reasons, and 30 retired on half-pay. A circumstance was alluded to by the lecturer which it is difficult to believe would have remained unremedied if the subject had been represented so as to be understood by the officials of the War Department under whose direction the establishment exists. It appears that there is only accommodation in the rooms where the practical hygienic studies are conducted for thirty-six gentlemen at one time, and that, in consequence the professors are compelled to divide the 100 probationers into three sections, so that only one-third of the instruction can be given to each probationer that was originally intended to be given, or that would be given, during the four months the session lasts, if there were sufficient accommodation for the whole number. Surely, means might be found for putting a stop to such a short-sighted arrangement as this appears to be! The lecture was attended by the whole of the staff of Netley, as well as by the probationers, and at the conclusion the officers and their friends adjourned to luncheon in the spacious mess-room at the officers' quarters.

UNIVERSITY COLLEGE, LONDON.—The examiners for the medical entrance exhibitions have recommended Mr. P. J. Edmunds, Mr. J. W. Carr, and Mr. J. H. E. Brock for the exhibitions of £100, £60, and £40 respectively. Mr. E. H. Thanes also obtained the number of marks qualifying for an exhibition.

ST. MARK'S OPHTHALMIC HOSPITAL, DUBLIN.—At a recent meeting of the governors it was stated that as the public account of this institution had been largely overdrawn, and there being no assets for the necessary expenditure, a number of the beds must be closed and admission refused to future applicants, unless immediate help was obtained from the public, so as to enable the hospital authorities to clear off the present debt, and to carry on the future work of this charity.

THE LANCET.

LONDON: SATURDAY, OCTOBER 9, 1880.

It is now fully twelve months since rumours were afloat that great changes were contemplated in the nursing department of Guy's Hospital by the governing body, without any consultation with the medical staff, and people wondered at the folly and shortsightedness of the authorities, who, upon so important a question, should attempt the introduction of measures dealing directly with the sick without a previous understanding being arrived at with those responsible for the care of the patients. But no sane person could then have foreseen that the changes referred to would have been carried out in spite of repeated and earnest remonstrance from the whole of the medical staff. As months rolled by and events occurred to give support to the arguments vainly raised by the staff, there were still some who thought that the governing body—all-powerful as they are—would view the question in the proper light, and would respect the grounds of opposition to their proposal which were so strenuously urged. No sign, however, came from the governing body, who a few months ago repeated their adhesion to the course they followed, and offered to the staff the compromise of two seats upon a weekly committee in which the medical vote would always be in a minority! The contention that the nursing department should primarily be under the control of the medical authorities has been ignored, and in a document (printed in another column) addressed to the Guardians of St. Saviour's parish, in response to a strong remonstrance from the Board, the Governors have appealed to the public, and, in doing so, have shown how great is the variance between them and the staff on this matter. The Governors have been praised for the "dignified silence" they have so long kept, but they would have consulted their dignity better had they long since listened to the remonstrances addressed to them, and not waited until their action (or inaction?) had called forth the indignation of a vestry board, followed up by the resolve to petition Parliament to inquire into the management of this great charity. We have no means of knowing whether the reply to St. Saviour's Guardians was supported by the whole body of Governors. It comes forth with the signature of the President, and must be held to represent the views of at least a large majority among them. It has seldom happened that so important a body has had to defend itself in such a manner for the policy pursued in the face of a resolute opposition. This policy is upheld to the utmost in the defence, and it closes with a scarcely veiled allusion to something worse to come if this policy is not suffered to be carried out. Never has the subordinate position held by the medical staff in a large hospital been more clearly manifested, and if good is to come of this long-continued scandal it will be by such a fundamental change in constitution as shall once and for ever free the medical staff from the humiliating conditions under which they are suffered to give their services to the sick, and to enhance the reputation of the institution.

It seems strange to read in this document that the Governors have always adopted the doctrine of the subordination of the nursing to the medical staff as a fundamental principle of hospital management; for during the months that have elapsed since the question came to the front, they have violated this principle by declining to accede to the reasonable demands of the medical staff upon the question of nursing. They say that conciliation was offered and rejected by the staff, who are depicted in this appeal to the public as swayed with one sole desire, born of unfounded prejudice—namely, the removal of a matron whom they disliked. It is hardly worthy, and certainly not dignified, of the Governors to impute such motives to their medical staff, who have waged war less against the matron than against the system of which she is the representative; and an admission is made which goes a long way to explain the determined and continued opposition of the staff. The Governors admit that "it was unfortunate that the opinions of the staff were not fully ascertained before any new rules were drawn up." Most unfortunate, truly! Such a statement only emphasises the more plainly the absolute impotence of the staff at Guy's Hospital in matters of management. It would have been at least courteous to have consulted them, and if concurrence rather than opposition in the new measures had been expected, such consultation would doubtless have taken place. It seems as if opposition were anticipated, and the strange belief were encouraged that the medical staff would quietly submit to any regulations dictated to them, although these would strike at the very matters in which they were most interested. They were not then suffered to know anything of the revolution which had been prepared for them in the department which most directly concerned the welfare of their patients; and the new *régime*, which led to the dismissal of many efficient and tried nurses, was instituted without their sanction and almost without their cognisance. It was not to be expected that a body of gentlemen, whose high personal characters, no less than their professional abilities, are guarantees of their honesty of purpose, fearful of the future of the great hospital in which they served, should have addressed many an urgent remonstrance to the governing body to reconsider the course they were taking. They knew well that the nursing department was capable of improvement, and would gladly have undertaken the task of inaugurating a new system; but they were not suffered to have a voice in the matter, and when they saw in what directions the so-called "reforms" were leading them they did all they could, and protested with one voice, against the evils they were powerless to avert. Their protestations and arguments fell on deaf ears. A policy had been planned out, and it was determined to carry it at all costs.

The Governors, in their elaborate defence, formulate the "rules," which they aver have proved so obnoxious to the medical staff, but we believe that it is not so much the rules themselves as the spirit in which they have been interpreted and the manner in which they have been enforced, that are the real grounds of dissatisfaction. It is absurd to think that objections could be raised, for example, to improved punctuality in attendance of nurses, their greater comfort, the introduction of trained nurses on night duty, the training of probationers, or even the adoption of uniformity

of dress among the nursing staff. If these were the real points against which the medical staff have raised their voice, they would deserve but little sympathy. But the Governors do not state how it came to pass that women who for years had been trusted and had proved themselves worthy of the confidence imposed in them, were turned adrift on trivial pretexts; nor how persistently the advocates of reform depreciated the "old" system to magnify the new; nor how palpably wanting in tact, judiciousness, and forbearance was the management they extol and support. The full details of the controversy have not been made public, but it cannot be imagined that the medical staff would persist, at the risk of misrepresentation and of wrongful imputations, in a unanimous opposition, did they not see with their own eyes how grave was the condition into which their hospital was drifting. The Governors say that friendly co-operation with the staff ceased from the first promulgation of the rules, and that they have failed to discover in what practical directions the staff have reason to complain of the improved system; and they seem to regard the fact that the wishes of the staff have been complied with in the times and attendance of nurses, as a great concession obtained "at some sacrifice of important considerations." What are these "important considerations"? Can they possibly outweigh the paramount necessity of the personal intercourse between the medical men and the nursing staff which ensures that the directions of the former shall be efficiently carried out by the latter? The public attacks upon the matron, to which the Governors allude as the only reply vouchsafed by the medical staff to these changes, were called forth by the inconsiderate zeal of that lady's friends, who have done their best to alienate the staff from her, and who would have served her better had they counselled courteous deference rather than covert opposition.

In the face of their treatment of the medical staff, it hardly becomes the Governors to appeal to the sympathy they have practically shown in the support of the school attached to the hospital—a school of world-wide celebrity. Of what use is it, if, whilst giving with one hand, they raise the other to deal a deadly blow at the interests of the school they profess to support? Still more unworthy of a governing body are the words that close this document, for they hint at the means still left them to compel acquiescence from the recalcitrant staff. They point out that the paramount end of a hospital is the relief of suffering, with which no "professional objects or struggles for power" should be suffered to interfere; and they add, with significance: "Keeping this end steadily in view, but also having special regard to other interests and feelings, the Governors have patiently persevered in efforts to avert consequences which have been for some time obviously impending; but they are not at liberty to evade the responsibilities of their position under an Act of Parliament, however painful their duty may be."

One word as to the duty of the staff. They have striven long and hard to gain their point, and this is all the encouragement they get. The one course, which to some unreflecting persons would seem the only possible one now, is, from many and obvious considerations, not open to them. They must continue in their office, and do their work in the treatment of the sick and the cause of medical science and

education; but they must not lose heart, or fancy that in doing so they are humiliated, or that in process of time their views, if reasonable, will not be adopted. They must labour strenuously to seek such an alteration in the constitution of the hospital as may for ever prevent the recurrence of so lamentable a state of affairs as that in which Guy's Hospital has been plunged for a whole year. Hard as the task will be, it is forced upon them by the conditions which impel them to remain at their posts; and we confidently believe that this long and painful controversy will bear its fruit in causing the inauguration of a system in which all questions of management concerned with the direct care of the sick shall be controlled by the medical authorities themselves. The constitution of Guy's Hospital is antiquated and effete, and it is time to appeal to Parliament to have it altered in conformity with the more enlightened modern spirit. It is from no class motive that we advocate such a change, but from full knowledge of the benefit which the sick poor would derive therefrom, and of the certainty that the hospital would thus be enabled to do its work more efficiently than under a system which practically places the whole management in the hands of one man, controlled only by a governing body composed of laymen, who are unable to understand or appreciate the proper functions of a responsible medical staff. The correspondence which was made public in *The Times* of Thursday last, between Mr. BRYANT and the President and Treasurer of Guy's Hospital, renders it only too painfully evident that all hope of an amicable settlement of this vexed question without an appeal to Parliament is now at an end. The position taken up by Mr. GIBBS is one of open defiance to the remonstrances of the medical staff. Meanwhile the rights and demands of the Faculty cannot be set aside or allowed to remain unsatisfied. The effrontery of the President's reply to Mr. BRYANT is evidently the outcome of ignorance, the sort of ignorance that induces or permits laymen to forget that a hospital is essentially a *medical* charity; in short, an institution in which the medical element must be naturally and inevitably paramount. The Governors of such an institution are simply persons of social position and repute entrusted with the guardianship of the property and general interests involved. The administration must in the nature of things be carried out in the spirit of the prime movers of the charity—viz., the medical men whose art and skill it is the sole object of the charity to bring within reach of the poor. It is an obvious perversion of the principle of hospital management to assume that the establishment is foremost, and the medical element accessory. As a matter of fact and principle, the establishment is simply an adjunct and agency of the medical department. It follows that the hospital must be administered for the medical faculty, and the nursing with every detail not purely financial ought to be subject to their approval or control. This is the point to make plain, and now that the issue is fairly and fully raised the Governors of Guy's Hospital must be prepared to see it carried to the highest tribunal and there confirmed. The time for compromise has passed.

It is very easy to disparage the institution of Introductory. And occasionally, it must be admitted, the institution seems a prosy and dull thing. There is a want of

aim and point and applicability in what is said. The Lecturer refers to nothing in particular, or to circumstances infinitely remote from the actual experience of the audience; or, if the speaker adheres to his subject, he does it with so little faith and freshness as to excite the interest neither of his hearers nor of his readers. When a batch of such Addresses has to be editorially considered, woe betide the unlucky speakers! How could an editor rise from the ordeal of reading such a series in a charitable frame of mind, and say else than that the whole institution of Introductorys should be abolished, and the student left to wade or plunge in *medias res* according to the lights of nature, with any stray instructions he could pick up from parents, friends, or fellow-students? It is in no such mood that we find ourselves undertaking to criticise the discourses of those who have this year discharged the much-feared duty of speaking introductory words to students beginning a new session, or, it may be, the very process of medical education itself. We find ourselves in a mood to praise the institution of Introductorys. Clearly the position of a young man on the threshold of the great Temple of Medicine is one needing sympathy and advice. He little knows what is before him: what tasks of mind; what dry labour; what multifarious details; what demands on his patience; what subtle temptations to be idle, to put off work to the end of sessions, till the approach of examinations, or to choose work that is easier or more inviting, instead of work that seems drier and less interesting—to be in the hospital or in the operating-theatre when he should be in the dissecting-room; or, worse temptations still, to be fast, or free, or forgetful of the restraints that are constituted by home and the presence of dear friends.

A man is only once in his life in the position of beginning medical study. And he is presumably placed in entirely new circumstances with new opportunities for going wrong and being selfish, and happily new occasions for doing work bravely, unselfishly, with reference not only to his own future success, but to the family convenience and the family fame. It is a supreme moment with a medical student at which he needs direction, and this direction should be in the Introductory which he hears, and the other Introductorys which he may read. And if the students take our advice, they will this year read them all. They are all pertinent, and they are all parallel. They show a common judgment on the part of teachers as to the present state of medicine, and the present way of learning it. The note which has been struck is so tuneful, so harmonious, that the medical work of the session should be happier and more hopeful, and altogether better for the Introductorys of 1880.

We scarcely know how to do detailed justice to the individual addresses—an inability which we have already atoned for by advising students to read them all, that they may be struck with the *consensus* of the advice given them. The different points insisted on by separate lecturers are not so noteworthy as the remarkable agreement on certain great principles underlying all existing views of medical education. Perhaps the Address of Dr. BURDON-SANDERSON is the most complete and scientific exposition of the motives and spirit which should actuate a medical student; of the foundations on which he should build his medical knowledge; and of the general nature of that knowledge as far as it has yet

been disclosed in response to laborious inquiry. But Dr. CAVAFFY'S Address is scarcely less valuable or complete. The fundamental idea of both Addresses is this—that the Medical Art is growingly becoming an affair of sound and minute knowledge, daily becoming more and more dependent upon science, that proficiency in it is not to be gained by any routine reading or “walking the hospitals,” but only by the minute study of what Dr. BURDON-SANDERSON terms the three “P.’s,” Physiology, Pathology, Practice. Dr. SANDERSON’S list of “P.’s” must even be extended if it is to include all that he and others think indispensable in the knowledge of an accomplished practitioner of medicine. There should really be four “P.’s,” thus, Physics, Physiology, Pathology, Practice. Not different from this was the view of Mr. WALTER PYE at St. Mary’s, who said that medicine at the present day was advancing, not as it had been for the last two hundred years, simply by the accumulation of clinical experience, but by striving as far as possible to reduce its practice to the condition of that of an exact science; and very practical and much needed was his advice to younger students to get their first professional examination over as soon as possible, and till that was done not to attempt to do any clinical work in the wards, an irregularity which leads to much grief and failure in examinations. Dr. GEORGE JOHNSON, at King’s College, spoke with authority on the importance of use and cultivation even for the highest natures, MILTON and SHAKESPEARE being brought into court as illustrations, and characteristically and effectively wound up in the classical words of Sir THOMAS WATSON. Dr. ORD very properly insisted that boys meant for the medical profession were not to have a school education different from others, and while vindicating the classics insisted on the introduction of medical sciences into school courses. Dr. DONKIN, at Westminster, claimed respect for accumulated clinical experience while insisting on the value of modern invention and research. Not the least valuable part of this lecture was the keen exposure of the very spirit of quackery, as illustrated in homœopathy and in exaggerated specialism.

Students entering such a profession as ours should do it humbly and yet proudly, humbly because of the limitations of their own capacity to deal with the knowledge that is waiting to be used and appropriated by them, proudly because of the lofty aims of their profession and the long roll of great and good men which have adorned it.

THE Metropolitan Hospital Sunday Fund stood very high in the estimation of the public before, but the meeting of Tuesday last confirms its claim to public respect. It is not difficult to secure an agreement of the various religious bodies in support of a philanthropic object; but to preserve that agreement while delicate questions of difference of creed have to be touched, and respect for the creed of poor patients has to be vindicated, is not so easy a matter. It looked at one time as if the admirable harmony which has characterised the proceedings of the Council in past years was in jeopardy; but good sense and high principle prevailed, and the meeting ended, if not in a perfect resolution, at least in one which maintains the fundamental laws of the constitution of the Fund, and the harmony of the members of the Council.

This happy result is due very much to the firmness and intelligence with which a few members of the Council have vindicated the laws of the Fund, and the principle that in all hospitals, even in those in which a high ecclesiastical element and purpose is most apparent, the religious opinion of patients must be respected. The Distribution Committee, led by Sir SYDNEY WATERLOW, cannot be congratulated on its appearance in this matter. In the first instance it was found napping most carelessly, and overlooking an obvious disqualification—namely, the want of a duly constituted committee—in a hospital claiming a grant. When it was made clear—when, in fact, it was confessed—that the hospital had not a committee, the Distribution Committee made light of the objection, and was disposed to override the rule, and give the grant on its own authority, and in violation of two rules of the Fund—first, that which requires that all hospitals sharing in the benefits shall have a committee; and, secondly, that which requires that any award, before being considered final, shall be sanctioned by the Council. Fortunately, the Distribution Committee determined to submit its views in the form of a report to the Council. Here evidently they thought to have an easy vote in favour of overlooking the absence of a committee, and making very light of the admitted instances in which very strange doctrines, and resort to the confessional, had been urged on patients. Professor MARKS, the Rev. Dr. RIGG, Dr. ALLON, and others, insisted in the firmest manner possible on the necessity of a committee, both as a condition demanded by the laws of the Fund, and as the only possible way of securing respect for patients and their religious creeds and convictions. The Rev. Mr. KITTO was disposed to think that the proselytising action complained of was the mere uncontrollable indiscretion of nurses or sisters, but the objection founded on the want of a committee, he admitted, was insuperable. The Distribution Committee then modified their resolution so as to postpone the granting of the award until the Lord Mayor shall be satisfied that a committee had actually been appointed in a constitutional way. All parties were anxious for a unanimous vote, and accordingly this resolution was accepted, though both the Council and the hospital would have been placed in a more dignified position if the claim had been rejected for this year and until the hospital had put itself fully into line with the rules of the Fund. The resolution, however, recognises the great principle that until an institution has a committee, it is not a public institution, and has no claim on a fund raised by a great public and unsectarian effort.

It is to be hoped that we shall hear no more of hospitals without committees. If such hospitals apply again to the Fund, there will be no excuse either for them or the Distribution Committee overlooking their disqualification. The strong assertion of the Committee principle by the Hospital Sunday Fund is a great gain, and will tend to stop many abuses, amongst others the tendency to use hospitals for ecclesiastical purposes. Patients should have the comforts of religion, but they should be absolutely protected from its controversies; and it would be simply shocking if bigotry, after being driven out of churches, were to find a place of refuge in hospitals.

Annotations.

"Ne quid nimis."

THE COMING SESSION IN EDINBURGH.

ON Monday the dissecting-rooms in the University New Medical Buildings were opened for the purpose of enrolling students, but work will not be begun until next week, since a few painters, &c., are still in possession. The chief hall is 108 ft. long, 39 ft. wide, and 27 ft. high, is well lighted, and ventilated. A second room measures 39 ft. in length, and 20 ft. in breadth; while annexed to these we find the lavatories, cloak-, bone-, and demonstration-rooms, together with assistants' private studies. The lecture-theatre, which is being pushed forward rapidly, will accommodate 500 students, and altogether the anatomical department seems constructed in a most efficient and comfortable style. The convenience of the student is also being seen to in the hospital, where it has been found necessary to enlarge the University Class-room of Clinical Medicine attached to the Infirmary. This was originally built to contain seats for 120 men, but the overcrowding last year was so great that the managers agreed to have it rebuilt at an estimated cost of £1200. The new class-room should be completed about the end of the month, and is expected to hold 300 students. The Government intend to proceed with the new class-room in the Botanic Gardens shortly. The extra-mural dissecting-rooms have also been opened, and there can be little doubt that the energy displayed by the lecturer in Minto House has acted as a healthy stimulus, contributing in no small degree to the activity seen in the rapid completion of the University buildings.

BLOOD FORMATION IN BIRDS.

OUR knowledge of the origin of the blood is almost entirely dependent on comparative physiology. Some light has been thrown upon the subject by the observation on the mammalia, to which we have from time to time called attention. The formation of blood in birds has now engaged the notice of one of the most distinguished workers in this field, Professor Bizzozero, who has published, in connexion with Dr. A. Torre, an abstract of the results obtained. The former had previously shown that, in certain mammalia, if anæmia is produced by venesection, the spleen becomes the seat of active formation of red blood-corpuscles. The object of the recent investigation was to ascertain whether this is also true of birds, in which hitherto almost nothing is known of the mode of origin of blood-corpuscles. The observers have found that, just as in mammalia, in the red bone-marrow of birds (fowl, pigeon, crow, dabchick, finch, wild duck, swallow, sparrow) there are numerous lymph-cells and red blood-corpuscles, in addition to the connective-tissue cells, bloodvessels, &c. The lymph-cells differ much in size, number of nuclei, &c. Especially noteworthy are certain lymph-cells which contain in their protoplasm numerous rod-shaped or oval corpuscles, highly refracting, like fat, but readily distinguished by chemical reagents. Such lymph-cells are abundant, both in the bone-marrow and the circulating blood, and their protoplasm appears to be particularly mobile. The red corpuscles of the marrow differ from those of the blood in that they possess no typical form, but are of different shapes, and seem, on comparison, to represent stages in the development of red blood-corpuscles. Spherical bodies are also seen, consisting of a large rounded nucleus, enclosed in a layer of thin coloured protoplasm. Near them are similar but larger bodies, still oval and somewhat flattened, with smaller nuclei and a larger quantity of enclosing protoplasm, and adjacent again are other nucleated cells of the size and form of typical red blood-corpuscles, distinguished

from them only by clearer protoplasm and delicate circumference. Two structures found by Bizzozero in the marrow of the mammal are wanting in that of the bird—the giant cells with central multiplying nuclei, and the cells containing blood-corpuscles in their interior.

The distribution of bloodvessels is nearly the same in the marrow of the bird as in that of the mammalia. Small twigs spring at acute angles from axial arteries, and divide into fine capillaries at the periphery of the marrow. From these arise a dense network of broad veins, limited by very delicate but distinct walls, which run centripetally, and open into an axial trunk. Fine sections of the hardened marrow show that all the cells which contain corpuscles with hæmoglobin lie within the veins, so that we must assume that only within these does the development of red corpuscles take place. Another peculiarity of the veins is the very large number of white corpuscles which they contain.

That the three cell forms above described are really stages of the development of red corpuscles can also be proved experimentally. When the bird has been rendered very anæmic by venesection, such cells are found in great numbers, not only in the marrow of flat bones, but also in that of some of the long bones. If a .75 per cent. solution of chloride of sodium be injected into the femoral artery, and the blood issuing from the "vena nutritia" of the tibia be examined microscopically, the corpuscles in question may be observed in numbers in this blood, while they can scarcely be discovered in that of the body generally. When sections of the marrow under these conditions are examined, it will be found that the peripheral part of the lumen of the vein consists almost always of layers of lymph corpuscles, so that the remainder of the lumen, occupied by the red blood-corpuscles, is very small. In the spleen of the birds rendered anæmic no transitional stages could be found, nor have these forms been found in the spleen of healthy animals. Thus it appears that the only organ in which their formation can be traced is the bone-marrow.

THE MIDDLESEX HOSPITAL.

At the opening of the session on the 4th inst. the distribution of prizes took place in the new theatre, A. H. Ross, Esq., M.P., presiding, in the unavoidable absence of H.R.H. the Duke of Cambridge. The customary introductory lecture did not take place, but the proceedings were opened by a brief and appropriate address from Mr. J. W. Hulke, F.R.S., who concluded his remarks by formally handing over the new buildings to the governors of the hospital. After the ceremony, a conversazione was held in the new buildings, which were decorated by Mr. Lichfield, and many works of art and scientific appliances exhibited by Messrs. H. Graves and Crawford, Messrs. Doulton, Hawksley, Murray and Heath, Meyer and Meltzer, Kröhne and Sesemann, Baker, Collins, and others. The new buildings comprise a spacious lecture-theatre, capable of seating 300 students, a lecturer's-room, and a dissecting-room, the site occupied by the old theatre being utilised for the latter, the result being a large and well-lighted room, admirably adapted for its purpose. In the evening the annual dinner was held in St. James's-hall, under the presidency of Dr. A. P. Stewart, one of the consulting physicians to the hospital. Amongst those present were Mr. Ross, M.P., Mr. Bell Sedgwick, Captain Bedford Pim, Professor Flower, Dr. Greenhow, Mr. Nunn, and the whole of the hospital staff. There was a very large attendance, about 120. The toast of the "Army and Navy" was proposed by Professor Flower, and responded to by Captain Bedford Pim, and Mr. Ross replied for the "Houses of Parliament." "The Middlesex Hospital" was given by Dr. Greenhow, and replied to by Mr. Bell Sedgwick. The chairman gave the "Middlesex Hospital Medical School," which Mr. Hulke acknowledged. Dr. Coupland proposed

the "Past and Present Students," responded to by Messrs. Oscar Clayton and P. T. Thane respectively. The "Health of the Chairman" was given by Mr. G. Critchett, and the toast of the "Middlesex Minstrels" by Mr. Nunn, replied to by Mr. G. A. Critchett, under whose direction the musical arrangements had been carried out. These included an original composition by Mr. Casson, entitled "Floreat Alma Mater," as well as selections from "Trial by Jury," and were admirably rendered by the "Minstrels." Herr Ganz presided at the pianoforte.

ANTHRAX.

AN important communication was made to a recent meeting of the Académie de Médecine by M. Bouley. M. Toussaint lately announced the discovery of a method of preventing anthrax in sheep. It was proposed to inoculate them with the blood of an animal suffering from the same affection, defibrinated and freed from bacteria by filtration. In order to test the correctness of the statements of the practicability of this method, M. Bouley obtained from the Minister of Agriculture twenty sheep, of which sixteen have been inoculated with the defibrinated and purified blood from a case of anthrax. Four of these animals immediately died with grave symptoms of anthrax, and the twelve others presented symptoms of illness so severe that it was thought at one time all would die. These results indicate no immunity from the effects of inoculation, but rather an innocuousness of the liquid employed. Successive and minute filtration, heating to 50° C., or the addition of a small quantity of carbolic acid, do not remove all the bacteria from the blood. They simply lessen their number to a very minute proportion, and if animals resist inoculation with blood so treated, it is because the germs of the disease are given in too small a quantity to cause fatal accidents.

The varying resistance of sheep of different races appears to be rather a question of susceptibility to dose than of absolute indifference. Some time ago M. Chauveau found that in inoculating with infected blood a series of sheep, there were always some which resisted, while others succumbed. He soon found that the refractory animals were always foreign—from Barbary. He found, however, that an inoculation of blood which would kill one of the indigenous sheep did not leave the foreign sheep unaffected. They presented mild symptoms, such as slight fever, swelling of the lymphatic glands, &c. If the dose of poison was increased these animals also perished. If, however, one of these Barbary sheep was repeatedly inoculated at intervals, the effects became slighter and slighter after each inoculation, and the animal ultimately became indifferent to the poison. Moreover, lambs born of ewes which were inoculated in this manner during the latter period of gestation seem to have acquired a greater immunity than that possessed by the ancestor. It is suggested that Barbary sheep, thus rendered secure, should alone be pastured on land in which the germs of the disease abound.

It is important, however, to remember that facts lately ascertained by Dr. Greenfield seem to show that animals very susceptible to the poison may have their susceptibility greatly lessened by inoculation with poison which has been rendered feeble by passage through the system of a rodent. The facts discovered at the Brown Institute, that the virulence of the poison can be thus lessened, and that it can thus be employed for successful inoculation, is one of the highest importance.

The disease is attributed popularly to effluvia from the land on which the disease occurs, but its origin seems to have been satisfactorily ascertained by M. Pasteur. He has proved that the germs of the disease—that is, the bacteria—are transported to the surface of the soil by earth worms. Having collected the excremental dirt thrown out by

earth worms on the surface of the soil in a locality where a cow dead of anthrax had previously been buried six feet deep, he obtained by cultivation a prodigious quantity of bacteria, which, being inoculated, readily produced the malady.

DEATH FROM CHLOROFORM.

ANOTHER case of death from the administration of chloroform is reported, this time from Hull. The patient was a man fifty-nine years of age, who was undergoing a second operation of lithotomy by Mr. Nicholson. Chloroform was administered on both occasions, and at the first sitting no ill effects were observed from the drug. When the fatal event happened the stone had already been crushed twice, and Mr. Nicholson was about to proceed to a third crushing, when his attention was called by his assistant to the patient, who appeared to have fainted. About two drachms and a half of chloroform had been administered. Artificial respiration was maintained for half an hour, but the heart did not act again. At the post-mortem examination this organ was found to be weak and flabby, especially the right ventricle. The examination of the bladder showed that it would have been necessary to have repeated the lithotomy several times before all the stone could have been removed. The coroner's jury returned a verdict of death from an administration of chloroform and weakness of the heart; that the chloroform was administered with all due precaution, and that the operation was conducted in a careful manner.

THE TERMINATION OF NERVES IN MUSCLE.

A MEMOIR on the interesting subject of the mode in which nerves terminate in muscle is contained in the part of the *Archives de Biologie* that has just been issued. It is from the pen of M. Foettinger, who has been engaged upon the subject for four years, and who has conducted his researches partly in the laboratory of M. Edouard v. Beneden in Liège, and partly in that of M. Engelmann in Utrecht. The muscles of insects were selected in preference to those of other animals, since the details of their structure are more easily recognisable under the microscope than those of other groups of the animal kingdom. The best preparations were obtained from the *Chrysomela cærulea*, a beetle which is common on various labiate plants, especially on the mints, from *Hydrophilus piceus*, *Lina tremula*, and the *Passulus glaberrimus*. The animals were placed in strong alcohol for some days, and the isolated fibres of the legs or trunk examined with various powers. Each fibre or primitive fasciculus presents several nerve-endings. In *Chrysomela* nine were sometimes found in the length of one millimetre, though this was an unusual number. In *Passulus* as many as five were found in one millimetre and a half, and in *Hydrophilus* six were found in one fibre. There seems to be no very definite rule either as to the part of the muscular fibre on which they are placed, or as to the number of muscle elements intervening between two of them. Sometimes their position is linear; at others they appear to be placed on opposite sides of the muscular fibre, whilst taking five of them successively it was found that the number of muscular elements between the nerve-endings was 23, 13, 21, and 14. These are usually conical in form, a nerve running to the summit of each cone. The cone itself is composed of granular matter, with nuclei interspersed through it, and it sometimes appears as if the granular matter was obscurely segmented into portions surrounding each nucleus.

The nerve-endings or terminal plaques, as M. Foettinger calls them, are situated on the surface of the fibre, and their free surface is covered with a thin, structureless, transparent membrane, continuous with the sarcolemma of the muscular

fibre on the one hand, and with the sheath of Schwann investing the nerve fibre on the other. The drawings which accompany the memoir exhibit the plaques as simply applied to the muscular fibre, no processes or fibrillæ penetrating it. He has noticed the interesting fact, which, however, had been previously noted by Arndt and Frédéricq, that in insects at least, contraction always begins in the muscular fibre at the plane of the cones, and at these points exclusively, and this fact may be shown to have an important bearing on the subject of *vis insita* of muscle. For since in microscopical specimens the transverse markings of the muscle are always found much more closely approximated just beneath the nerve-ending than elsewhere, it is reasonable to suppose that if a nerve-paralysing agent like curara were administered to the animal, and if the effect of his agent were really, as is usually admitted, on the intramuscular portion of the nerve, the transverse markings should not present the approximation in question beneath the cone alone, but at any part of the contracted fibre indiscriminately. Unfortunately insects cannot be rendered motionless by curara. The point may perhaps be worked out with better success with the muscles of mammals.

THE HOLDEN TESTIMONIAL.

THE ceremony of presenting Mr. Holden's portrait to Mrs. Holden took place on Friday last in the great hall of St. Bartholomew's Hospital, in the presence of a large assembly of ladies, governors, and past and present students of the hospital. Mr. Savory, in presenting the portrait, alluded in eloquent terms to the long and valued services which Mr. Holden had rendered to the hospital, its medical school, and to the profession at large. Mr. Holden acknowledged his deep appreciation of the gift, and requested, on behalf of Mrs. Holden, that the treasurer and the governors of the hospital would accept the portrait as a gift from herself, and that they would allow the portrait to be placed in the committee room in company with the portraits of those who had in former years rendered distinguished service to the hospital.

THE MEDICAL NIGHT SERVICE IN PARIS.

We regret to learn that a difficulty of a sort sufficiently familiar here when charitable aid rubs shoulders with aid which individuals have to provide for themselves is beginning to trouble the course of the newly-organised medical night service in Paris. The physician who is called upon to make a night visit receives a fee of five francs, paid by the Administration in the case of indigent persons, and presumably by the persons receiving the aid in the case of the well-to-do. It is found, however, that many of the well-to-do evade payment of the fee, and that to meet the unanticipated deficit thrown upon the administration, its yearly credit will have to be increased from 50,000 to 60,000 francs. In order to put some check upon this abuse the Commissioners of Police have been instructed to give particulars as to the recovery of fees from those able to afford them who have recourse to the medical night service.

FATTY TUMOUR BENEATH THE SCALP.

MR. SYDNEY JONES writes us:—"The following case, on account of its rarity, seems worthy of being put on record. A boy, aged twenty months, was sent to me on September 21st, 1880, by Dr. Torr, of Old Kent-road, with a tumour of scalp as big as the half of a good-sized orange. It was first noticed at two months old, and was then the size of a small marble, and had increased, of late rapidly, to its present size. It occupied the median line, was over the sagittal suture, and extended backwards to the situation of the posterior fontanelle. It gave a sensation of fluctuation; firm

pressure upon it did not cause any diminution, nor any head symptoms or other inconvenience; but the child's crying seemed to make it somewhat tighter and more prominent. The margin was raised, and harder than the rest of the tumour. On the 28th of September, with a grooved needle I removed small particles which showed, under the microscope, pure fat. On September 30th I transfixed the tumour longitudinally, and removed it. It was adherent in places to the scalp, and was peeled off the pericranium, to which it was accurately moulded. It weighed $2\frac{1}{2}$ oz. It consisted of pure fat; the margin was more dense than the rest, and curiously crenated. The child did well; the wound being dressed antiseptically."

WESTMINSTER HOSPITAL.

THE staff and some of the past and present students of the Westminster Hospital Medical School dined together at the Langham Hotel on Friday last, after the opening of the session earlier in the day. Dr. Octavius Sturges occupied the chair. Among the visitors was Dr. Magrath, Provost of Queen's College, Oxford, who had previously distributed the prizes at the afternoon gathering. In returning thanks for the toast of his health, he expressed his great interest in medical education, and his high estimate of the part his University is playing, in giving a sound preliminary training; unfortunately, he was unable to say that it did more than this.

"CASTRATION FOR HYSTERIA."

UNDER the above title a French journal gives an account of a case which was presented to the Berlin Medical Society some months ago, and which has scarcely attracted the attention in this country which its significance deserves. Dr. Israel presented to the Society a young woman twenty-three years old, cured of severe hysteria by "Battey's operation," of which she bore the cicatrix. The patient had suffered for some years from obstinate vomiting, accompanied by severe ovarian pains. She became extremely weak and anæmic. Many surgeons advised the operation, and she gradually arrived at the conviction that castration was the only remedy for her sad state. The operation was performed under chloroform "with all antiseptic precautions." During the first three days after the operation there was extreme tenderness in the lower part of the abdomen, and the ice was obliged to be constantly applied. At the same time there was retention of urine, which only passed off at the end of twelve days. A week after the operation the vomiting had ceased, and the pain in the ovarian region had disappeared. The patient's cure remained permanent. One detail, however, of this beautiful illustration of the value of "oöphorectomy" remains to be mentioned, and it is not unimportant. The operation was a pretended one. A superficial wound only was made! The result certainly justified the means.

THE MEDICAL SOCIETIES.

THE following are the dates at which the respective London Societies commence their sessions: Obstetrical on October 6th; Clinical, 8th; Medical, 18th; Pathological, 19th; Medico-Chirurgical, 26th. We trust that the forthcoming session will be productive of much activity in these bodies, which may be regarded as the centres of London medical science.

THE NINE ELMS ACCIDENT.

THE case of Watson, the engine-driver, has been noticed in THE LANCET as being one of trephining for a punctured wound of skull. His head symptoms progressed very favourably, and the wound, treated antiseptically, was rapidly healing. Some old lung mischief, however, was relighted by the damage to which he had been subjected,

and rapidly assumed extensive and fatal proportions. He died on Sunday, the 3rd of October.

REMOVAL OF THE ENTIRE SCAPULA.

MR. BELLAMY informs us that he removed the scapula at Charing-cross Hospital, on Saturday, Oct. 2nd, for an enchephaloid growth, involving the whole bone. The hæmorrhage was but trifling, owing to the perfect command obtained over the subclavian artery, by compression, through a primary incision in the integuments. Up to this date the patient has been progressing most favourably.

CIRCULARS have been issued by the hon. secretary of the Medical Society of London, Mr. Malcolm Morris, requesting Fellows of the Society who have seen cases of arsenical poisoning by means of wall-papers &c., to forward the notes of such cases to 63, Montague-square, and at the same time to communicate the names of any professional friends who may be interested in the inquiry.

FROM statistics published by the society for promoting the use, as food, of the flesh of the horse, ass, and mule, it would appear that hippophagy is steadily increasing in Paris. In 1866 the aggregate weight of such flesh consumed was 171,300 lb.; in 1879 the quantity had risen to 1,982,620 lb. In the French provinces also the practice seems to be growing in favour.

MR. THOMAS DOLAN, F.R.C.S., has undertaken to give the first course of lectures in connexion with the Halifax centre of St. John Ambulance Association. The lecturer took for his subject on Oct. 1st "The Outlines of the Anatomy and Physiology of Man."

"CONTAGION" has been chosen by Dr. E. Symes Thompson as the subject of the Gresham Lectures this year, to be delivered at the College, Basinghall-street, on Oct. 12th and three following days.

AT the annual meeting of the Faculty of Physicians and Surgeons of Glasgow, held on the 4th inst., Dr. Robert Scott Orr was elected President, and Dr. Robert Perry, Visitor of the Faculty.

MISS PYNE, late of the Edinburgh Royal Infirmary, has been appointed Lady-Superintendent of the Westminster Training School for Nurses and Matron of the Westminster Hospital.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

A METROPOLITAN POLICE-COURT.

AT a recent meeting of the Fulham District Board of Works, Dr. N. C. Collier, the medical officer of health, presented a report on the prison-cells of the Hammersmith Police-court. The report was prepared at the request of a jury, who had held an inquest on a prisoner named Marchant, who had died in Clerkenwell prison, after having been confined in the cells at the Hammersmith Court. The request had been conveyed to Dr. Collier by the coroner, Dr. Hardwicke. Dr. Collier's report showed that the woman Marchant was retained in the police-cells at a time when some sanitary alterations were being carried out; but whether she contracted the fever of which she died at that time could not be stated. There are only five cells for the reception of all the prisoners taken to the court. Each cell contains an area of 481 cubic feet, which is not more than

sufficient accommodation for two persons, whereas as many as eight prisoners are at times confined in a cell. There is literally no ventilation except a small iron grating over the door, which is quite inadequate for the purpose. With eight persons confined in a cell, there would be only 96 cubic feet of air space for each prisoner. The amount allowed under prison regulations is not less than 200 cubic feet for each prisoner. It seems strange that better accommodation should be allowed to prisoners after they are convicted than before trial, when by law they are, for the time being, innocent. In each cell, close to the door, there is a watercloset. This amounts to positive indecency when several persons are confined together in a cell. The urinal and closet accommodation to the court is very unsatisfactory, the former being so badly constructed that it is impossible to avoid indecent exposure. Here is an apartment termed the "strong room." It contains an area of 6655 cubic feet. It is used at times for the reception of as many as 94 prisoners and 60 constables. This gives only 79 cubic feet of air space to each person. Such an amount of overcrowding is highly prejudicial to health. The court itself is quite inadequate for the purpose for which it is used. It contains an area of 199,821 cubic feet. On one day when Dr. Collier had the number of persons counted, there were 350 in attendance at the court at 11 A.M. The ventilation is from the roof, and is certainly insufficient, and the ventilation starlight is never lighted. Dr. Collier expressed the opinion that the atmosphere of the court is such as to be highly prejudicial to the health of those persons who are constantly exposed to it. The whole sanitary condition of the place is highly unsatisfactory, and the accommodation of the court quite inadequate for the requirements and the great and increasing population of the district. The Board directed that a copy of the report should be sent to the Home Secretary.

FREE HOSPITALS FOR CASES OF INFECTIOUS DISEASE.

The *East London Observer* raises the question of free hospitals for the reception of cases of infectious disease. It puts the case in the following striking manner:—"The common sense of the case may be put in a few words. We will instance a man living in one or two rooms in a house filled with other lodgers. He is attacked by fever. If he is promptly removed to hospital there may not be another case in the same house, but if financial considerations have to come into the account, the removal to hospital may be delayed or not take place at all, with the probable consequence that the disease may be communicated to others who are really too poor to pay for their treatment, and who may not only be temporarily but permanently pauperised as the result of their affliction. Would it not be better in such a case for the first person attacked to feel free from any anxiety on the score of payment for hospital accommodation, so that he might, without delay, enter the hospital and avoid the danger of becoming a centre of infection in a thickly-populated neighbourhood? To haggle with a man about cost of maintenance in such a case is a penny-wise-and-pound-foolish policy, and to seek to wring from one who, under ordinary circumstances, has his energies fully tasked to supply food and raiment for his family, payment for hospital treatment, is, to our thinking, an injustice. The individual who, attacked with infectious disease, at once seeks the shelter of the hospital, is really doing a service to society. Why, then, should he be fined for the consideration he shows for others, by removing himself—the centre of infection—from their midst?" Clearly our contemporary is right. The greater the facilities which can be given for the admission of cases of infectious diseases into hospital, the better control shall we have over the spread of contagion among the community at large.

BARMOUTH.

Barmouth is a beautiful summer resort on the Welsh coast, and, like too many of these resorts, has been so satisfied with its natural advantages as to hold it perfectly unnecessary to supplement them with artificial ones. The air, the sea, and the soil might well be left to themselves, so far as wholesomeness is concerned, if it were not for the town; and here comes the rub. Barmouth is as other towns, and Barmouth people as other people—that is to say, they have a natural proclivity to create dirt, and when it is created to live amidst it. Barmouth the locality is delightful; Barmouth the town is offensive, and, if it is to maintain a decent reputation for habitability, must mend its ways.

The place, indeed, has become so bad that even its own citizens are raising their voices against it. This, indeed, gives great promise for amendment, for improvement is hopeless unless the citizens take it in hand. Local government is the central feature of sanitary administration, and local government means government by the inhabitants. We have before us the *Barmouth Advertiser*, which tells a most unsavoury story of the sanitary shortcomings of the town—a story which, we should imagine, would cause a rapid thinning of the long list of "visitors" printed in another part of the same journal. The journal professes to give only "a few of the most obvious abominations of the place." The few include foul drains, fouler sewage tanks, filthy deposits of refuse (and even the rare spectacle of a dead donkey among this will, we imagine, scarcely prove seductive to visitors), filthy pigsties, &c. If these be the few, what will the many be? Let Barmouth look to its sanitary state before the next summer comes.

"WASTING CESSPOOLS."

Chertsey is in difficulty with the Thames Conservators as to the disposal of the sewage of the place. Hitherto this has been passed into the river, but now the local authority is forbidden to do this, and has to seek some alternative method of disposal of the liquid filth. It proposed to effect this by establishing a system of "wasting cesspools" so-called; in other words, providing for the construction of cesspools which would admit of the filth hitherto passed into the Thames *soaking into the subsoil beneath and amidst the houses*, and from which a considerable amount of the drinking water of the town is collected in shallow wells! This astounding proposition, emanating from a so-called sanitary authority, was brought to the knowledge of the Local Government Board, and Mr. Netten Radcliffe was despatched to the spot. On inspection of Chertsey, he appears to have found that the filth to be withdrawn from the Thames, and proposed to be added to the filth deposited in the subsoil beneath the town, could not make that much filthier than it had already been made by privy pits and cesspools, and that "a wasting cesspool"—that is, a cesspool which shall permit the escape into the soil of everything that can flow from it—is the standard method of sewage disposal adopted in the place. Mr. Radcliffe had an interview with the rural authority as to their heretical proposition, and we now learn that they have set it aside, and that, influenced by the Local Government Board, they have determined to construct a proper system of sewerage for Chertsey.

THE LOWER THAMES VALLEY SEWERAGE.

The Local Government Board still keeps silence as to the Lower Thames Valley Sewerage scheme, and the Corporation of Kingston has got restless at being kept so long in doubt about the matter. At a recent meeting of this body the question of the present position of the Corporation with reference to the scheme was considered, and a deputation appointed to wait upon the President of the Local Government Board with regard to the following subjects:—1. The penalties about to be incurred under the Thames Conservancy Act, 1857 and 1864, and the Thames Navigation Act, 1866. 2. The uncertainty prevailing with reference to the decision of the Local Government Board as to the application to sanction the scheme of the joint board. 3. To ascertain whether the Local Government Board is prepared to concur in releasing the borough from the joint board. 4. To ascertain whether the Local Government Board is prepared to sanction the carrying out of a scheme for dealing with the sewage of the borough, either separately or in conjunction only with the districts immediately adjoining.

INFECTION!

A postman of Lambeth has been attending his wife ill of small-pox in the periods of absence from his duties. What is to be done? Here is a man distributing contagion with his letters, to say nothing of a promiscuous dissemination as he passed along the streets. Some members of the Vestry suggested prosecution, others, and happily a larger number, thought there were probably other considerations than punishment in view, and that the intervention of the magistrate would hardly mend matters, particularly if the postman lost his employment. No doubt it is undesirable to have individuals attending upon cases of small-pox de-

living letters among us, but if the community must have safety from danger of this kind, it must ensure the persons immediately concerned from want and from loss. Hitherto local authorities have, as a rule, considered the cost of precautions involving these considerations is a greater evil than the contagion from which safety is sought, and so long as this feeling prevails we must not hope to be able to shut out chances of contagion of the nature in question. At any rate, the magistrate's intervention would merely add another evil to the original one, without helping much to the removal of the latter.

THE METROPOLITAN CEMETERIES.

A Parliamentary Return has been printed giving several interesting details respecting the metropolitan cemeteries. It shows the acreage of the several cemeteries, the number of funerals that have taken place in each before 1852 and since 1852, the number of dwelling-houses situated within 200 yards of each cemetery, the number of persons permitted to be interred in one grave, and the drainage of the cemetery.

A DEVONSHIRE "WATERING-PLACE."

It is reported that the water-supply of Paignton, a health-resort in Devon, has been found to be derived in part from a duck-pond, which acts also as the sewage receptacle of a farmyard and house. The report, as a contemporary says, will doubtless be read with interest by the surviving visitors to that place.

The Vestry of Mile-end Old Town have had under consideration the offensive state of the water of Regent's Canal in their district. A case was mentioned of a house abutting on the canal, the owner of which had been thrice ill with fever, and whose medical attendant had threatened refusal of certificates of illness to his friendly society unless he removed from the vicinity of the canal.

The Local Government Board has directed the attention of the Stepney guardians to the fact that 13 per cent. of the births in their district are not accounted for in the returns of their vaccination officer, and requested an explanation of this large amount of arrears.

The Local Authority of Aberdeen have been taking measures to prevent the letting of underground rooms as living apartments, in contravention of the provisions of the Public Health (Scotland) Act, 1867.

Mr. J. Lawrence Hamilton, L.R.C.P. Ed., M.R.C.S. Eng., is a candidate for the post of medical officer of health and public analyst for Marylebone, vacant by the death of Dr. Whitmore.

It is reported that an outbreak of enteric fever has occurred in Rochdale, suspected to have arisen from the dissemination of the infection in milk, and that the disease is spreading.

The Commissioners of Sewers of the City of London have, at the suggestion of Dr. Sedgwick Saunders, determined to appoint additional meat inspectors.

The Local Government Board for Ireland have sanctioned a loan of £8000 to the Armagh urban sanitary authority for waterworks for that town.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

English urban mortality showed a marked decline last week. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5070 births and 3060 deaths were registered last week. The births were 115, and the deaths 215 below the average weekly numbers during 1879. The deaths showed a further decline of no less than 406 from recent weekly numbers, and the annual death-rate per 1000, which had been equal to 25.4, 25.0, and 24.1 in the three preceding weeks, fell last week to 21.3, a lower rate than has prevailed in any week since the middle of July. The lowest death-rates in the twenty towns last week were 12.5 in Plymouth, 16.6 in Bristol, 16.7 in Portsmouth, and 18.1 both in Birmingham and Sheffield. The rates in the other towns ranged upwards to 26.4 in Salford, 28.2 in Liverpool, 28.9 in Leicester, 30.0 in Hull, and 31.7 in Sunderland. The high rates in the three last-mentioned towns were

mainly due to excessive zymotic fatality. During the thirteen weeks ending last Saturday, the death-rate in these twenty towns averaged 23.2 per 1000, against 23.8 and 18.3 in the corresponding periods of 1878 and 1879.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 1009 and 912 in the two preceding weeks, further declined to 657 last week; of these, 399 resulted from diarrhoea, 108 from scarlet fever, 57 from fever (principally enteric), and 50 from whooping-cough. The annual death-rate from these seven diseases averaged 4.6 per 1000 in the twenty towns, and ranged from 1.4 and 1.9 in Plymouth and Portsmouth, to 9.8 and 11.6 in Sunderland and Leicester. Scarlet fever showed the largest proportional fatality in Sunderland and Norwich, and enteric fever in Norwich and Leeds. Ten of the 16 deaths from diphtheria in the twenty towns occurred in London. The 399 fatal cases of diarrhoea showed a decline of 212 from the number returned in the previous week and were equal to an annual rate of 2.8 in the twenty towns. The death-rate from diarrhoea, which did not exceed 1.6 per 1000 in London, averaged 3.9 in the nineteen provincial towns; the highest death-rates from diarrhoea last week were 7.7 and 9.6 in Hull and Leicester. Small-pox caused two deaths in London, one in Liverpool, and not one in any of the eighteen other towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 116 and 105 at the end of the two preceding weeks, further declined to 95 on Saturday last; 22 new cases of small-pox were, however, admitted to these hospitals during the week, against 27 and 6 in the two previous weeks. The Highgate Small-pox Hospital contained 8 patients on Saturday last.

The deaths referred to diseases of the respiratory organs in London, which had been 124, 153 and 174 in the three preceding weeks, further rose to 199 last week, and exceeded the corrected weekly average by 10; 121 resulted from bronchitis and 51 from pneumonia. The annual death-rate from lung diseases was equal to 2.8 per 1000 in London, and to 5.4 in Liverpool.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 18.8 per 1000, against 20.3 and 18.9 in the two preceding weeks; this rate was 1.5 per 1000 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 17.0 and 17.6 in Greenock and Glasgow, to 21.5 and 23.4 in Edinburgh and Perth. The fatal cases of the seven principal zymotic diseases in the eight towns, which had been 163 and 153 in the two preceding weeks, further declined last week to 134; they included 51 from diarrhoea, 33 from scarlet fever, 18 from diphtheria, 17 from fever, 9 from whooping-cough, 6 from measles, and not one from small-pox. The annual death-rate from these seven diseases averaged 5.4 per 1000 in the eight towns, and was 0.8 above the average rate from the same diseases in the twenty English towns. The zymotic death-rate in the Scotch towns last week ranged from 3.9 and 4.5 in Perth and Aberdeen, to 7.1 and 7.5 in Leith and Aberdeen. The fatal cases of diarrhoea in the eight towns, which had been 69 and 53 in the two previous weeks, further declined to 51 last week, and were equal to an annual rate of 2.1 per 1000; in the twenty English towns the diarrhoea death-rate last week averaged 2.8 per 1000. The largest proportional fatality from diarrhoea in the Scotch towns occurred last week in Edinburgh and Dundee. The deaths from scarlet fever in the eight towns, which had been 45 in the previous weeks, declined to 33 last week, of which 17 occurred in Glasgow, 12 in Edinburgh, and 3 in Dundee. The 17 deaths referred to fever showed an increase of 8 upon the number in the previous week, and included 7 in Glasgow, 3 in Edinburgh, 3 in Paisley, and 2 in Greenock. Of the 18 deaths reported from diphtheria, five less than in the previous week, 11 occurred in Glasgow, and 3 in Leith. The deaths attributed to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) were 76 in the eight towns last week, against 61 and 68 in the two preceding weeks; the annual death-rate from these diseases last week was equal to 3.1 per 1000 in the eight towns, against 2.5 in London.

HEALTH OF DUBLIN.

Excessive mortality again prevailed in Dublin last week. The annual death-rate in the city, which had been equal

to 39.3 and 38.5 in the two preceding weeks, was equal to 36.0 last week. During the thirteen weeks which ended on Saturday last the death-rate in the city averaged no less than 34.6 per 1000, against 21.3 in London and 21.5 in Edinburgh. The 217 deaths in Dublin last week included 63, or 29 per cent., which were referred to the seven principal zymotic diseases, showing, however, a further decline of 8 from the high numbers returned in the two previous weeks; 33 resulted from diarrhoea, 10 from fever, 9 from scarlet fever, 4 from measles, 6 from whooping-cough, 1 from small-pox, and not one from diphtheria. The annual death-rate from these diseases was equal to 10.5 per 1000 in Dublin, whereas it did not exceed 3.3 in London and 7.5 in Edinburgh. The 33 fatal cases of diarrhoea in Dublin showed a decline of 11 from those returned in the previous week, and were equal to an annual rate of 5.5 per 1000; the death-rate from diarrhoea in London did not exceed 1.6 last week. The 10 deaths from fever, including typhus and enteric or typhoid, exceeded the number in any week since the beginning of June. The deaths from scarlet fever were considerably less numerous than those in the previous week, while those from measles and whooping-cough showed but slight variation. Last week's return exhibited but a slight decline in the rate of infant mortality in Dublin.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

STREET IMPROVEMENTS AND ARTISANS' DWELLINGS, METROPOLIS.

An important communication on Street Improvements and Artisans' Dwellings in the Metropolis to the following effect has been addressed by the Home Secretary to the Metropolitan Board of Works. Sir William Harcourt states that he had anxiously considered the applications with reference to the various improvement schemes, and especially with reference to Sir R. Cross's letter of the 19th December, 1879. He fully appreciated the difficulties which the Board of Works had to contend with, and while he was most anxious to assist them and facilitate the carrying out of improvements, he at the same time could not forget that he was specially charged by the Act to protect those who could not protect themselves, and to take care that no extensive displacement of persons of the working-classes should be effected until provision was made for their being housed elsewhere. The Board themselves had suggested that the matter should be brought before Parliament next year in the shape of a Bill to amend the 33rd section of the Metropolitan Street Improvement Act, 1877, and obtain a full inquiry by a Select Committee into the whole matter, especially whether powers should not be given to the Board to erect suitable buildings on the various sites, instead of only having the power to lease them, which led to so much delay and difficulty; and while the law remained as it was, the Secretary of State was willing to adopt the suggestion by Sir R. Cross in his letter on the 19th of December, 1879, that if the Board would proceed by stages he would be ready to consider an arrangement whereby successive portions of the land might be cleared as soon as in each as houses had been erected sufficient to provide a number equal to the number displaced. Therefore, in answer to the letter of the Board on the 20th June last on the subject of the Newport Market Improvement Scheme, the Secretary of State was of opinion that the Board should at once take steps to acquire the whole of the property known as Newport Market site, and that the sites in Coppice row and Old Pye-street, intended to be appropriated, but not yet actually appropriated for working men's dwellings, could not be accepted by the Secretary of State as a provision for suitable accommodation. The Secretary of State was willing that the buildings on the Newport Market site should be taken down in successive sections, and to Section 1 being taken down immediately, but after that he could not permit any further demolitions until by the erection of additional buildings, either on Section 1 or on some other suitable area (to be approved by him), working men's dwellings had been provided sufficient to give accommodation for a number equal to the number of those displaced from Section 1, and the same rule must be applied to the other sections successively. If the Metropolitan Board of Works acceded to that arrangement, it would be convenient that they should at once submit to the Secretary of State for his approval a division of the area into sections. With reference to the

Tooley-street Improvement Scheme, the Secretary of State authorised the pulling down of the block of houses there which had been vacated by their inhabitants. As regards the Gray's-inn-road Improvement Scheme, he must withhold his consent to the displacement of seventy-seven persons until the Board are in a position to assure him that the plot, part of which it was proposed to let for the erection of labourers' dwellings, and which it was said would accommodate 300 persons, had actually been let for that purpose. The Home Secretary agreed to the Clerkenwell Improvement Scheme.

SANITARY ORGANISATION IN RUSSIA.

The zemstvo of Korsown, in the government of Simbirsk, have decided to establish a new sanitary organisation of their district. To this end they have decided to divide the district into eight sub-districts, to be administered by the delegation of the province in conjunction with the Medical Council and sanitary detachments. The staff of each sub-district will consist of a physician, a midwife, and several assistant medical officers. Each township, it is proposed, shall have attached to it an assistant medical officer. The general management of the organisation will be devolved upon a mixed body of medical and lay representatives of the district—some honorary, others appointed by the zemstvo. Honorary members will be required to pay twenty-five roubles yearly, and will have the privilege of entry into the hospitals and ambulances of the district. They will be expected to inform immediately the Medical Council of the appearance of any epidemic in their locality, and to keep a watch over its general sanitary state. Two general meetings will be held in the course of the year—one in February, the other in July, and special meetings will be convoked in the event of the appearance of any epidemic. The attention of the general meetings will be given to the means of augmenting the pecuniary resources of the organisation, the supervision of the public health, measures to be taken against epidemics, the introduction of vaccination, the amelioration of hospitals and ambulances, the relief of the poor, medico-topographical studies and vital statistics, the regulation of medical fees and the fees of midwives, and the general sanitary requirements of the district. A general meeting of the medical men of the district will also be held yearly, at which all will be required to be present. The purchase of instruments and drugs will rest with the Medical Council. The funds necessary to cover the expenses of the organisation will be derived from the following sources: the zemstvo, the rural townships, the Imperial Government for the treatment of soldiers, the provincial delegation, private donations, and the annual subscriptions of members.

THE HEALTH OF INDIAN GAOLS.

We learn from *The Indian Medical Gazette* that Dr. Lethbridge's report on Bengal gaols for 1879 reveals an appalling tale of sickness and mortality. In an average population of 18,483, 947 were constantly sick; there were 23,368 admissions into hospital and 1752 deaths, of which 341 were caused by cholera. These figures give rates per mille of 51, 153.4 and 94.8, which are almost unprecedented in the recent history of Bengal gaols. The Lieut.-Governor has expressed his conviction that the chief cause of the increased sickness was the adoption of the diet scale proposed by the Prison Conference and recommended by the Government of India. Steps are being taken to remedy this, "but it is terrible to reflect," says our contemporary, "that so much suffering and death have been caused by a mistake which ought in these days to be impossible."

The sanitary condition of Preston has been the subject of a long discussion by the Town Council. It was stated that four years ago 400 houses were, on account of their unwholesomeness, closed by the Health Committee, and now others are being dealt with in a similar manner. The authorities would appear to be determined to do their work thoroughly, for the inspectors have, it seems, been ordered to "make an inspection of every house in the town."

From New York we learn that yellow fever had broken out on board the British barque *Ermagh*, bound from Port de Paix for that city. Two of the crew had died from the disease, and had been buried at sea, and the vessel had to be towed into port from want of hands to work the ship.

The last received number of Medical Reports issued by the Imperial Maritime Customs, China, contains two important papers, one on "Cholera Epidemics in Japan," by Dr. D. B. Simmons; the other, entitled "Additional Notes on Filaria Sanguinis Hominis and Filaria Disease," by Dr. Patrick Manson. To both these papers we shall refer in detail hereafter.

Mr. John Gay appeals, through *The Times*, for wood pavement for the foot-paths of our roads as well as the carriage-ways. It would be "less noisy, damp, and chilly," and so enhance much the comfort of that large section of wayfarers, the walkers.

The Warsaw section of the Red Cross Society has founded in the environs of the city a Maison des Invalides, which is to be opened on the 21st February, 1881.

A medical congress has been summoned in the province of Tchernigow, to discuss the measures to be taken against the spread of diphtheria.

MANIFESTO OF THE GOVERNORS OF GUY'S HOSPITAL.

On Sept. 30th, at the ordinary meeting of St. Saviour's guardians, held at the workhouse, John-street West, Blackfriars-road, Mr. J. Mitson presiding, the following communication was received from the governors of Guy's Hospital, in acknowledgment of a resolution with reference to the recent proceedings in that institution sent to them by the board of guardians:—

"Extract of proceedings held at a general court of governors on Wednesday, Sept. 29th.

"Read, a memorial from the guardians of St. Saviour's, dated September 10th, and resolved that the following answer be sent thereto:—The governors of Guy's Hospital acknowledge the receipt of the memorial of the guardians of St. Saviour's Union. The governors must observe that they cannot recognise any responsibility on their part to the guardians of St. Saviour's, Southwark, nor can they undertake to enter into any correspondence, however friendly, with any similar body; but they think it important to the interests of the great institution over which they preside to make known what they conceive to be the truth, that they request attention to the following observations:—The governors fully appreciate the interest taken by the guardians in the good name and high position of Guy's Hospital, and their sense of the benefits which it has conferred on the large population which the board represents. The guardians state that 'they have heard with real concern that the governors have determined to make the physicians and surgeons subordinate to the nurses.' The governors are not aware of the source from which the guardians can have received such information. They can only state for themselves that the subordination of the nurses to the express orders of the physicians and surgeons in all matters involving or affecting medical or surgical treatment is, in their opinion, a fundamental principle of hospital management; that they are determined to maintain that principle; and that no suggestion for a departure from that principle has reached them from any person in or out of the hospital.

"The general arrangements for the supply of persons fit to be trained as nurses, for the health and training of such persons, and for assigning to them their posts in the hospital, involve questions of great complication and difficulty, including the domestic relations and duties of nearly 150 women of various social ranks, which call for much tact and judgment in administration. In all the alterations which have been made, the sole aim of the governors has been the increased welfare of the patients, and during all the discussions between the medical staff and themselves their object has been to 'conciliate,' without any desire to assert unduly the power placed in the hands of the court as the controlling authority of the hospital.

"Last autumn the late matron resigned her office after thirty-four years of approved service; and Miss Burt, who had for six years discharged with great credit the offices of superintendent of the Leicester Infirmary and of the Training Establishment for Nurses, was invited to undertake the duty. She entered on her duties on Nov. 1st, 1879, and at once, under the instruction of the treasurer, proceeded to

deal with those points on which improvements had been for a long time past admitted to be necessary. It was unfortunate that the opinions of the staff were not fully ascertained before any new rules were drawn up. It was, however, still more unfortunate that a prejudice had been raised throughout the hospital against the matron a month before she came—viz., on Sept. 26th. The rules which had been prepared for the guidance of the nurses were, in consequence of the alarm raised in the wards, misinterpreted as soon as they were issued.

"The rules were intended to secure more punctual attendance in the wards, to remove all excuse for doing any work in the wards not directly beneficial to the patients; to provide orderly and comfortable meals for the nurses; to prevent the nurses leaving the wards for recreation at undesirable hours; to distribute the work done in the wards so as to secure a thorough training of probationers of whatever social rank; to diminish the menial work of the trained nurses, which had been a serious hindrance to their proper duties in former times; to provide for the night nursing by fully-trained nurses, and, consequently, to require that trained nurses should take their share of night work, a point on which, through misconception, there has been much controversy; a uniform dress for the several classes was also prescribed.

"No new measures had been introduced which in any way diminish the authority of the head nurse (or sister, as she is called in the Act of Parliament which in 1724 established the hospital), or encourage nurses to act on their own responsibility, irrespective of the medical authorities; nor is there any justification for the suggestion that the orders of anyone of the medical staff with respect to a patient under his care are not, and have not been, implicitly and immediately obeyed.

"The governors observe the importance attached by the guardians to the 'spiritual life of the patients,' but no rules whatever exist in relation to it which can, as the guardians suppose, override the medical treatment of the patients, or in any way affect the efforts of the medical staff. In this respect things continue on precisely the same footing as heretofore. The following is the only new practice adopted in religious matters. Short family prayers are read from a manual issued by the Christian Knowledge Society, at which the day nurses attend before they go to breakfast and to their morning duty, and after they come off in the evening. The night nurses also after coming off duty attend the short daily service in the chapel, which has always been held there. Friendly co-operation between the staff and the executive authority appears to have ceased from the first promulgation of the rules, and although the governors have endeavoured to the best of their ability to remove misunderstandings, and by careful and protracted inquiry to discover in what practical matters the staff have reason to complain of the general competency and conduct of the nurses, they have not been able to make the discovery. They have only met with what seem to them exaggerated inferences from a few particular occurrences, repeated over and over again, or general denunciations of the abstract principle of some supposed new system alleged to have been introduced.

"The governors have endeavoured to comply with the wishes of the medical staff as to the allocation or retention of nurses in particular posts, and as to the regulation of their hours, so as to suit the convenience of the physicians and surgeons, though at some sacrifice of important considerations. But these and other overtures of conciliation have been met by renewed acts of opposition, either in the form of collective protests or of attacks in the public journals, and by peremptory demands for the dismissal (as the only condition of peace) of an officer whose intentions and acts the staff, in the opinion of the governors, wholly misapprehend, who earnestly desires their assistance and advice, but with whom they refuse to communicate, notwithstanding repeated entreaties to them to meet her personally.

"The governors are not aware of any obnoxious rules or arrangements which need modification, but if at any time any such need should arise, the weekly committee appointed by the governors will give the medical staff, through the representatives they have been requested to select, the opportunity for making their requirements known. If, however, the medical staff do not attend—still more, if they refuse to attend—the weekly committee, it is not possible for the governors to deal with requirements which the medical staff do not afford them the obvious means of dealing with.

"The guardians may rest assured that the governors are not unmindful of the reputation of the eminent men whose researches have gained celebrity for the school attached to Guy's Hospital. The governors, acting on the recommendation of the late and present treasurer, have given very substantial proof of the interest they take in the school by the expenditure of many thousands of pounds within the last few years. But, important as the advancement of medical research may be, and undoubtedly is, in a professional and even in a national point of view, it must not be forgotten that the primary object of a hospital is the alleviation of the ever-present sufferings of the sick poor. The welfare of many charitable institutions might be imperilled if an impression should gain ground in the public mind, however ill-founded, that any professional objects or struggles for power stood in the way of cordial co-operation among all classes of persons entrusted in various degrees with responsibility for the successful attainment of this paramount end. Keeping this end steadily in view, but also having special regard to other interests and feelings, the governors have patiently persevered in efforts to avert consequences which have been for some time obviously impending. But they are not at liberty to evade the responsibilities of their position under an Act of Parliament, however painful their duty may be.

"H. HUCKS GIBBS, President."

THE HOSPITAL SUNDAY FUND.

DECISION IN THE MATTER OF THE EASTBOURNE CONVALESCENT HOSPITAL.

ON Tuesday the Lord Mayor presided over a meeting of the Council of the Hospital Sunday Fund, held in the long parlour of the Mansion House, to receive and, if advisable, adopt the Special Report of the Distribution Committee upon the case of the Eastbourne Convalescent Hospital. The question, which was raised at a previous meeting, and the discussion of which has excited no small interest, was one which, it will be remembered, related to the expediency of making a grant of money to this hospital, in which it was alleged that an objectionable system of proselytising had been and was being carried on amongst the patients. The whole matter was referred to the Distribution Committee to consider and report upon, and the result of their deliberations was embodied in the brief report presented to the General Council on Tuesday. Amongst those present were Alderman Sir S. H. Waterlow, Mr. Alderman M^rArthur, M.P., Professor Marks, Rev. Canon Spence, Mr. Few, Rev. R. J. Simpson, Rev. M. S. A. Walrond, Mr. W. R. Tidd, Mr. J. Boodle, Dr. Glover, Mr. Pitcairn, Rev. J. Toulson, Dr. Sedgwick Saunders, Sir F. Lycey, Rev. Dr. Kennedy, Rev. Dr. Allon, Rev. Dr. Rigg, Mr. Gervase Smith, Bishop Claughton, Bishop Beckles, Rev. Dr. Finch, Sir R. Alcock, Mr. Jabez Hogg, Rev. J. F. Kitto, Mr. A. Willett, Dr. Stewart, Mr. Custance (sec.), &c.

The minutes of the previous meeting having been read and confirmed, the secretary, Mr. Custance, submitted the report of the Special Distribution Committee, recommending that the Lord Mayor be asked to pay the award originally made to the Eastbourne Convalescent Hospital.

Alderman Sir S. H. WATERLOW said that as Chairman of the Distribution Committee it devolved upon him to ask the Council to accept the resolutions come to by that committee, and, in conformity with the substance of those resolutions, to ask the Lord Mayor to pay the award which the committee had originally recommended in the case of the Eastbourne Convalescent Hospital. Before making this request in formal terms, he trusted that he might be excused if he said both for himself and, he believed, for all the members of the Distribution Committee, that he felt it would be very unwise on any future occasion to call upon the members of the Distribution Committee to make inquiries into the detailed method by which religious consolation was administered within the walls of hospitals and convalescent homes to which grants were made by the Council of the Hospital Sunday Fund; for this was a duty which they would not be able to discharge with any kind of satisfaction to themselves or to other parties. He felt that the Hospital Sunday money was collected from persons of every shade

of religious opinion—from Jew and Greek, from High Church, Low Church, and Nonconformist,—and all of these were naturally in close sympathy with the forms of their own worship, and with the hospitals and convalescent homes under their control, whatever might be the form of the religious consolation therein administered. However, the Council having requested the Distribution Committee to make inquiry in this case, they had devoted themselves to the task—they had heard Dr. Glover, and had listened to the remarks of the deputation which waited upon them from the hospital. And here he felt bound to say what he had not said in originally moving the adoption of the committee's report—viz., that the Eastbourne Convalescent Hospital was managed with greater economy than any other hospital or dispensary to which a grant was made—more economically upon the basis by which the Distribution Committee arrived at the relative cost of management of each of these institutions. The Eastbourne Convalescent Hospital came out under 2 per cent. lower than any other hospital. On the other side, he was bound to add that the Eastbourne Hospital was not managed by a committee of the character contemplated by the Council in Rule 4 of their rules, which said that "Those hospitals and dispensaries only which are managed by a committee duly constituted, and which produce their printed reports with balance-sheets duly audited for the last three years, shall be allowed to participate in the fund." The committee, when making their grant, had not, he feared, been so careful as they should have been in their inquiries upon this head. They felt they should have communicated this to the Council. However, the authorities had promised that there should be a properly constituted committee before another year had passed. In answer to a question put by a member of the Council, Alderman Sir S. H. Waterlow said that the patients of the hospital were practically London patients, and he proceeded to say that he had, on his own account, gone down by express train to visit the hospital, had been admitted and conducted over the institution, and the impression left upon his mind was that the work of the hospital was being done as well as it could be done. The patients were simply required to attend a short morning and evening prayer; and he found, moreover, that the gates of the garden were left wide open, and the patients allowed to go out to any place of worship they liked. In conclusion, Alderman Sir S. H. Waterlow moved that the resolutions of the committee be received, and that the Lord Mayor be asked to pay the award originally granted to the Eastbourne Convalescent Hospital.

The Rev. CANON SPENCE seconded the motion, concurring with the remarks made by Alderman Sir S. H. Waterlow, which he believed were characterised by good sense and feeling. The adoption of this resolution would do a great deal to persuade the public that their Fund was a reality, and that it was intended to benefit, not one, but all religious denominations.

Professor MARKS, dwelling upon the expediency of observing respect towards the private opinions of patients in matters of religion, said he had gathered an impression which had been confirmed by an article he had read in THE LANCET, that in this institution advantage was taken of persons being in a weak state of mind and body, to induce them to leave the one church to which they were attached, and join another. This was a very wrong proceeding. It was contrary to the wishes of the Board and—although he was a Jew who said it—it was he believed contrary to Christian practice. He spoke of this, because it was a matter to be inquired into. They afforded accommodation to persons of all religious denominations who were unfortunate enough to be obliged to enter, but certainly the bodily weakness of a patient should not be employed as an opportunity for urging his acceptance of any other than his own actual religious opinions.

Mr. FEW was of opinion that the Council were not to ask about these matters. Nothing of a religious character was done at this hospital without the sanction of the bishop. He regretted extremely the remarks which had been made, and believed that the Council would find themselves in a most unpleasant pass if they were to go through the hospitals for the purpose of inquiring how they were conducted. He hoped the motion would be adopted, that the public might be assured that the Council did not concern themselves in these questions. If their movement was to succeed, they must—although he was sorry to say it—discard wholly questions relating to the soul.

The Rev. Dr. ALLON heartily agreed with the principles

just expressed, but disagreed with the application of them which was attempted to be made. They had nothing to do with the internal religious management of any hospital, except to see that the regulations of every hospital contained a clause exempting patients from coercion in religion. If this affair was passed over, and a sufficient guarantee not given that it should not occur in the future, he for his part could not consent to give another collection to the fund; and he believed that he spoke for many other Nonconformist ministers. (Hear.) But there was something else to be considered. They had no power to make this grant. They could not make it except in direct violation of their own fourth rule.

Alderman Sir S. H. WATERLOW, in reference to this objection, called the attention of the Council to the circumstance that for two years past they had made a grant to the Hospital of St. John and St. Elizabeth, although the mode of government of that institution still differed somewhat from that prescribed by the rules.

The Rev. Dr. RIGG said that such procedure lent probability to the complaints that grants were made to hospitals not under committee management. It was a grave question how far they had a right to make a grant in this case, for here they were dealing, not with an actual Catholic institution, but with an institution professedly of the National Church, where it was said that there existed *in petto* the principles of Catholicism. The defence of Mr. Few, that nothing was done without the sanction of the bishop, was a very weak one. Their proper course was not to make a grant to this hospital until it was placed under a committee.

The Rev. M. S. A. WALROND contended that the bishop had given a particular sanction in this case, after a particular investigation. As regarded the religious tone which prevailed in particular institutions, this was generally known to the patients at the time that they entered. Letters to hospitals were very frequently given by ministers, and if a dissenting minister sent one of his congregation to a High Church Home, he had no right to expect that the patient would receive dissenting religious instruction.

Sir FRANCIS LYCETT, opening up a question on the subject of Mr. Carter's pamphlet, the "Guide to Heaven," said to have been placed in the hands of patients in the Eastbourne Hospital,—

Alderman Sir S. H. WATERLOW rose to a point of order. He explained that that matter had been investigated by the committee, and that it had been made clear that the authorities had condemned the sale of the book. It was in 1876—nearly four years ago—that a copy was sold to a patient; the person who sold it had been sent away, and the chaplain who permitted the sale of it had since left the hospital. The authorities had expressed their entire disapproval of the transaction, and a stringent rule had been made upon the subject.

The Rev. F. KITTO asked Alderman Sir S. H. Waterlow whether, to the satisfaction of the Distribution Committee, there was any proved case of religious coercion? Was it approved by the governing body? If a case had occurred, it might have been an isolated one, in which event, he thought, the Council might be going a little further than was necessary in such circumstances.

Alderman Sir S. H. WATERLOW said it was proved that a copy of the book referred to was sold. The sale, so soon as discovered, was repudiated by the authorities.

The Rev. F. KITTO: In what way are the Council going to undertake to regulate the religious zeal of all servants, and all visitors of all hospitals to which we are going to make a grant?

Dr. GLOVER: Through a committee.

The Rev. F. KITTO said that no committee could possibly undertake such a charge. The committee could not say that in isolated cases the rule would not be infringed. A single servant might bring about a position of conflict with the Fund. They should all set themselves strongly against religious coercion, but they ought not to withhold a grant from any institution because a particular servant might have erred against the rules.

The Lord Mayor was about to put the question to the meeting, when

Dr. KENNEDY rose, and said that he had been a member of the Council from the first, and what had always seemed to him to be one of the pleasantest characteristics of their proceedings was the entire absence of anything like sectarian feeling on the part either of the Church or the Dissenting community. But after the speech of Mr. Walrond it was quite impossible for him and others to co-operate with the

Fund if the principle of that speech were to be adopted—viz., that they had no right to interfere with the religious instruction of hospitals, unless in cases where such instruction interfered with the bodily condition of the patients. And this, he might say, he did not understand; for it was not to be supposed that if Professor Marks, for instance, were given leave to instruct a patient in the principles of Judaism such instruction would act in an unfavourable way upon the physical system of the person instructed. Professor Marks had laid down the true principle to be observed, and if that principle were not observed, then the sooner the Fund were broken up the better. The principle he referred to was, that while the Council were not to interfere with the religious instruction of any institution which received assistance from the Fund, they were to require that no hospital should encroach upon the religious liberty of any of its patients. However, in any case it was not competent for them to make this vote, on account of the non-existence of any such committee of management as the rules of the Council required.

The LORD MAYOR said, that the motion having been modified he would ask to be allowed to put it to the meeting as it now stood, believing that its adoption would end a painful discussion.

The motion, as modified, read as follows:—"That the resolutions of the Distribution Committee be received; and that the Lord Mayor be asked to pay the grant originally proposed to be made to the Eastbourne Convalescent Hospital, as soon as he shall be satisfied that a properly constituted committee has been appointed."

The motion in this form was adopted with unanimity, and the meeting separated.

THE SERVICES.

INSPECTION OF THE ARMY HOSPITAL CORPS.

Sir William Muir, K.C.B., Director-General of the Army Medical Department, visited Aldershot on Tuesday last and made an official inspection of the dépôt of the Army Hospital Corps, and of the classes of officers and men who have undergone instruction in bearer column drill. The class of officers numbered twenty-eight of the young surgeons who have recently passed through Netley with several officers of older standing. The class of non-commissioned officers and men was 100 strong. After the parade movements, which, owing to the wet weather, were of necessity very brief, the Director-General proceeded to the training school class-room, where the officers were examined by Surgeon-Major Sandford Moore in military law and the interior economy of a regiment. On the termination of the inspection, which Sir William Muir pronounced very satisfactory, the Director-General and his staff were entertained at luncheon by Surgeon-General Fasson and the officers of the Army Medical Department in their mess-room.

MEDICAL OFFICERS FOR INDIA.

Surgeon-Majors Caleb S. Wills, C.B., James Hector, K. W. Cummings, E. O'Sullivan, H. J. O'Brien, Charles Haines, J. Fraser, with Surgeons W. H. Garde, D. Leckie, and Isaac Emerson, embarked for service in India in H.M. troopship *Serapis* on the 3rd inst.

The following medical officers are mentioned in despatches for good service in the action of Palkao Shana, in July, 1880, by Major-General Hills, V.C., C.B.:—"Surgeons W. R. Murphy, 19th Bengal Lancers, and P. F. O'Connor, 1st Punjaub Cavalry, deserve special thanks for their care of, and attention to, the wounded on the field, often at much risk to themselves, from straggling and skulking Afghans."

We regret to report the death, on August 25th, at Peshawur, East Indies, of Surgeon W. A. Daubeney, Bengal Medical Service. Dr. Daubeney had only very recently arrived in India, and after a short time spent at Allahabad was ordered up to Peshawur, where he committed suicide a few days after his arrival.

The cholera in India has, we are happy to say, nearly disappeared amongst the troops. Our advices received by the mail of Monday last report that with the exception of a few

sporadic cases at Lucknow and Allahabad, the European Army is free from that disease.

Alfred Allen, M.D., has been appointed Acting Surgeon to the 1st Lincolnshire Corps of Light Horse, Volunteers.

ADMIRALTY.—The following appointments have been made:—Fleet-Surgeon W. A. Lloyd, M.D., to the *Nankin*; Fleet-Surgeon D. O'Connor, and Surgeons A. R. Joyce and J. A. McAdam, to the *Superb*; Fleet-Surgeon J. F. Mitchell to the *Lord Warden*; Staff-Surgeon S. Sweetman to the *Brilliant*; Staff-Surgeon J. D. A. Harvey to the *Royal Adelaide*; Surgeon J. Jennings to the *Asia*; Surgeon H. M. Levinge, M.B., to the *Belleisle*; Surgeon F. R. Loftie to the *Hercules*; Surgeon W. M. Long to the *Agincourt*, additional; Surgeon D. B. Bookey to the *Cambridge*; Surgeon John Hunter to the *Flamingo*; Surgeon A. W. Russell to the *Zephyr*; J. A. Spencer to be surgeon and agent at Rutland, Arranmore, Cruit, and Cruit Head.

Correspondence.

"Audi alteram partem."

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—Professor Clay tells us, in your number of last Saturday, that he "feels justified in stating that uterine cancer may be removed by Chian turpentine."

In THE LANCET of the 19th of June I wrote, that having treated eight cases with Chian turpentine, I had found no effect whatever from its use. In the article of Saturday Mr. Clay has thus alluded to some of the cases to which I referred. He says: "In an institution in this town the impure drug was first used, when, after a trial of the pure drug for about three weeks, letters appeared in a medical journal, declaring that the remedy was of no benefit in the treatment of cancer." Mr. Clay infers, therefore, that sufficient time had not elapsed for the admittedly pure drug to have produced any well-marked beneficial result.

That the professor is wrong in his facts with regard to the turpentine used in the Women's Hospital by my colleagues and myself, the subjoined letter from Mr. Lawson Tait, will, I think, abundantly prove. But for the sake of argument, admitting him to be right, allow me to remark that in the only four cases of which he had given any detailed account, and upon which his advocacy of the remedy seems (see THE LANCET, March 28th) to be chiefly based, most clearly marked and surprising results were recorded as having been observed in an even shorter period.

His first case was one of "scirrhus of the cervix and body of the uterus, in which hæmorrhage was excessive, pain of the back and abdomen agonising, and the uterus was so extensively destroyed by the cancerous ulceration that its cavity readily admitted three fingers." Mr. Clay tells us that in four days "she was greatly relieved from pain, the os was quite contracted, and would scarcely admit the finger, and the surrounding swelling or cancerous infiltration of the cervix much reduced."

In his second case, in which "the os and cervix were enlarged from carcinoma, to the size of a hen's egg, the os dilated, and the cavity of the cervix filled with epithelial growths, sacral pain severe, and hæmorrhage had been continuous for six weeks." On the seventh day "the pain was entirely relieved, the hæmorrhage stopped, and the patient in excellent spirits." The turpentine acted upon the growth with great vigour in this case, "literally melting it away in four or five weeks."

The third case, one of epithelioma of os, cervix, and body, in a woman of fifty-two. "The mass larger than a cricket-ball, almost filling the vagina." On the fourteenth day "the swelling of the os and cervix was diminished, and the tumour, rough and shrunken, did not project so much."

In the fourth case, an epithelial cancer, "the size of a goose's egg,"—"so rapidly diminished that by the sixteenth day it had almost entirely disappeared."

Now, Sir, with these results before me—results utterly unequalled in the annals of therapeutics—results well-marked, definite, and unequivocal—and all in sixteen days, I may be excused for feeling sorely disappointed when the

same drug, the same formula, and under (as far as possible) the same conditions, I found my own results simply negative. However, I have up to this time deliberately and conscientiously persevered in the use of the drug, and I have now a large number of patients who are taking it. My cases, which have all been open to the observation of my colleagues, include the three classes referred to by Mr. Clay, "scirrhus," "epithelioma," and "ulceration after previous operation." I grieve to have to say that in no case has there been relief of pain, suppression of hæmorrhage, or diminution of the diseased tissues. In short, I may repeat emphatically the conclusion expressed in my letter of June 19th, that "in no case has the progress of the cancer been checked or in any way affected by the use of Chian turpentine."

In conclusion, let me add that although I have inquired carefully as to the effect of the treatment in the hands of others, I can hear of no successful case, except the one published in THE LANCET of July 3rd, by Dr. Drury, who, however, in answer to my questions this week, writes that his patient is dead "having succumbed to a dysenteric attack." Dr. Drury offers no hypothesis as to the causation of the "dysenteric attack," but expresses himself "quite satisfied with Chian turpentine." I am not! Now, Sir, the utter discrepancy between Mr. Clay's results and my own is so remarkable, that I am willing to believe that it must be due to some circumstances which, in spite of all my care, have been overlooked; I shall therefore be glad if he will allow me to place a case or cases entirely and completely under his management, in order that all possible sources of fallacy may be excluded! Or, on the other hand, I, or one of my colleagues, will, with his permission, watch any of the many cases now under his care in the Queen's Hospital.—I am, Sir, your obedient servant,

J. HICKINBOTHAM.

DEAR HICKINBOTHAM,—In answer to your inquiry I may say that I have, both in hospital and in private practice, been consulted in quite a number of cases, nearly approaching twelve, which have been under Mr. Clay's treatment by Chian turpentine, and in Mr. Clay's own hands, without in any instance benefit of any kind having been derived. These include cancer of breast, vulva, rectum, and uterus. Besides these, I have, as you know, tried the drug in a large number of hospital cases, many of which you have seen, without in any instance having observed benefit of any kind from it, not even the relief of pain, in a single instance.

The drug used had been approved by Mr. Clay, having been submitted to him by Messrs. Southall; and it is not true, as stated by Mr. Clay, that the right drug had been used for only three weeks. The sample first supplied, and which had not been submitted to Mr. Clay, was hardly used at all, for most of it was wasted in futile efforts to make the sulphur pills.

Yours truly,

LAWSON TAIT.

Great Charles-street, Birmingham, Oct. 4th, 1880.

THE IMMEDIATE TREATMENT OF STRICTURE OF THE URETHRA.

To the Editor of THE LANCET.

SIR,—As bearing upon the discussion that is now taking place in your columns on Holt's operation for stricture by divulsion, permit me to quote the following paragraph from a lecture of mine, published over two years ago:—"I have practised this operation (Holt's) on something like seventy cases. I never met with any difficulty in performing the operation; I have never had a fatal result; it has never been followed by serious hæmorrhage or other distress, such as extravasation of urine; and though I cannot speak as to the ultimate result in anything like the majority of my cases, I know of many patients upon whom I operated eight and ten years ago who are living in complete comfort and, to all intents and purposes, are rid of those urgent symptoms which necessitated this mode of treatment."

Since this was published I have increased the number of my cases thus operated on to over one hundred, my conclusions remaining the same.

I therefore regret that I cannot agree with Sir Henry Thompson and other speakers at the Cambridge meeting in their estimate of this plan of treating strictures.

The large number of bad cases of stricture presenting

themselves at the Liverpool Infirmary furnish varieties which require corresponding modifications in treatment, and these modifications include internal urethrotomy as well as simple dilatation. I do not limit myself to any one plan of treating strictures; I see good in several.

There appears to be a hesitation on the part of some of your correspondents in making the assertion that internal urethrotomy is never followed by a fatal result. Are we to infer that it is never fatal in their hands?

I am, Sir, yours truly,
REGINALD HARRISON.
Liverpool, October 2nd, 1880.

THE PERIOD AND INFLUENCE OF INFECTION.

To the Editor of THE LANCET.

SIR,—In a discussion at the Sanitary Congress, and in the course of various inspections of the dwellings of the poor in different towns, I have been struck with the necessity for a clear and authoritative definition of the period after an infectious or contagious disease during which it is desirable that a patient should be isolated to avoid risk to his neighbours. In the case of children this is, of course, of the highest importance. At present great pressure is brought to bear upon parents by teachers with the view of securing the attendance of children at the schools inspected by Government. If one medical attendant proves obdurate he often loses a patient, as another more pliant doctor is summoned, who at once sanctions the raising of the quarantine. Let me give a typical example. It came under my notice last week. A laundress with a family has a child suffering from scarlet fever. Her medical attendant insists upon her giving up washing till all danger of contagion has passed. She submits to this for a brief period, and then getting impatient she dispenses with the attendance of her old medical man, and calls in another. The second comes proves more amenable to her arguments. Washing is renewed, and the child is despatched to school. After a brief interval the child is once more in bed with renal dropsy. Yet the medical attendant who did his duty loses his patient and his reputation, the cry being "Don't send for Dr. A—, he will keep your child in the house for six weeks, but call in that nice Dr. B—, who will send the patient to school within a fortnight." There is therefore great need for the College of Physicians to lay down a definite period for each of the infectious diseases during which it is desirable that a patient should be isolated. By fixing a maximum and a minimum time for each some discretion will be left to the medical attendant, and great scandal and dangers to the public health will be prevented.

I should like to ask in this connexion if surgeons object to have cases of typhoid fever in the same wards or in the same building with cases of recent operation? If so, on what ground is this objection based?

I am, Sir, yours, &c.,
HENRY C. BURDETT.

Seamen's Hospital, Greenwich, S.E., Oct. 2nd, 1880.

IRELAND.

(From our own Correspondent.)

At a meeting of Convocation of the Queen's University in Ireland, to be held this week, a resolution will be proposed to the effect that the dissolution of the Queen's University in Ireland, as contemplated by the University Education (Ireland) Act, 1879, would be a grievous infraction of the vested rights of the graduates of the University, and injurious to the best interests of academical education. Further, that an earnest appeal should be made to the present Parliament and to the Government to reconsider the position of the University, and that the Committee of Convocation be instructed to take steps by deputation or otherwise to give effect to this resolution.

The report of the President of Queen's College, Cork, for the Academic Session 1879–80 states that the previous session was in every respect the most prosperous the College had seen; but that not only had this prosperity continued,

but there had been a substantial increase in the number of students this year over last year. In 1849 the College opened with 70 matriculated and 45 non-matriculated students, or a total of 115; in 1879–80, being the thirty-first session, there were 271 matriculated and 29 non-matriculated, or a total of 300 students in attendance. Anywhere this would be considered as a successful result; but taking into account the exceptional condition of the south of Ireland as regards wealth, the needs for University education, and the low condition of preparatory education, not to speak of the difficulties arising out of religious views, the position already attained by so young a university college is eminently satisfactory.

The inquiry into certain irregularities in the management of the Kilmainham Small-pox Hospital terminated on the 30th ult., and Dr. MacCabe's report will be duly forwarded to the Local Government Board. Evidence was given generally corroborating the charges brought by the patient Lavery, to which reference was made in THE LANCET last week; and it was shown that the guardians, from economical motives, did not employ paid nurses, the sick being looked after by pauper inmates. Keeley, the wardmaster, who was principally implicated, although summoned did not appear, and the matter will be brought under the notice of the Local Government Board. Dr. MacCabe, who conducted the inquiry, suggested that some better arrangements should be made as to the keeping of the patients' clothing, the providing a hospital uniform, a better system of cooking, and the prevention of the abuse of stimulants.

The Committee of Management of the Cork Fever Hospital have held a very close and searching inquiry into the various matters affecting the management of the institution, which were disclosed at the recent public investigation. The proceedings were private, but the report of the committee is expected shortly to be forthcoming.

WE have received the following from the Hon. Secretary of the South of Ireland Branch of the British Medical Association:—

At a special meeting of the branch, convened to express an opinion on the recent investigation into the charges preferred against Professor H. Macnaughton Jones, the following resolutions were unanimously adopted:—

1st. "That this meeting of the South of Ireland Branch of the British Medical Association heartily sympathise with Professor Jones in the trying ordeal which he had to undergo in defence of his professional character in the recent investigation held in the Royal Cork Institution; and we beg to congratulate him on the triumphant vindication of his professional conduct on the occasion in question."

2nd. "And that we express in the strongest manner our condemnation of the recent proceeding, where a member of our profession was put on his trial before the public for alleged malaproxia and mismanagement in the treatment of a patient submitted to his care in the Cork Fever Hospital, whereas the only thing chargeable to him was having utilised the most recent medical knowledge at his command for the treatment of what was apparently a hopeless case; and we believe that such an attempt to interfere with a physician's skill and discretion is unfair, unconstitutional, and opposed to the best interests of the public, who benefit most by the progress of medical science. While thus expressing our opinion on the mode of procedure, we cannot fail to recognise the patience and great intelligence which was paid to the case by the Hospital Committee."

3rd. "That the hon. secretary be directed to forward the foregoing resolutions for publication to the *British Medical Journal*, THE LANCET, *Medical Press and Circular*, and the Cork local papers."

D. B. O'FLYNN, M.A., M.D.,
President of the Local Branch.
T. GELSTON ATKINS, B.A., M.D.,
Hon. Secretary.

PARIS.

(From our own Correspondent.)

M. DUJARDIN-BEAUMETZ entertained the Academy of Medicine last Tuesday with an account of his experiments in "xylotherapy." He finds that different kinds of wood possess different degrees of "æsthesiogenic" power, when

applied to the skin of an anæsthetic member. The experiments in question were, of course, made upon a few hysterical women; and the conclusions arrived at are of as much scientific value as are generally such deductions. "When a disc of wood is applied to the skin of these patients the following phenomena are observed after a variable time: first, the subject complains of the constriction produced by the cord used to fasten on the wood; then she feels the disc itself, and if it is then removed the skin is found to be redder and warmer than the neighbouring parts; moreover, the punctures which have been previously made to ascertain the degree of sensibility now bleed, and those which are now made are felt most plainly." Chinchona bark is the most efficacious, and next in order come thuya (*arbor vitæ*), rose-wood, mahogany, pitch-pine, nutwood, maple, and apple-wood. Violet-ebony (*pallisandre*), ash, poplar, and sycamore have no action at all, at least so it would appear at present; but xylotherapy is still in its earliest infancy, and it would be rash to affirm that they have not, perhaps, some action *à distance*. Those who have followed up the vagaries of metallotherapy will remember that an indifferent metal served to "fix" the sensibility when superimposed upon the "æsthesiogenic" metal which restored it. If his patients are able to guess at the object in view, M. Dujardin-Beaumez will, no doubt, find that the inactive woods have similar "fixing" properties when applied over chinchona, mahogany, or any other lignous disc. *Apropos* of metallotherapy, this science is about to enter upon a new phase. No publication upon the subject has as yet been made, but a manufacturer of electrical instruments tell me that he has recently constructed a number of electrodes of different metals for a prominent member of the profession. If electricity has not hitherto been a panacea for all diseases, it is, no doubt, because it has not been applied properly.

The electricity of the future will be guided by the light of metalloscopy. When this process has divulged the idiosyncrasy of the patient—say, for instance, gold or silver—galvanisation through gold or silver electrodes will give a satisfactory result. One may venture to anticipate that a very long name will be given to the system, and that it will be peculiarly applicable in certain neuroses, which are always best treated when left alone.

M. Pasteur's unexpected appearance at the last meeting of the Academy of Medicine gave M. Jules Guérin an opportunity of asking a number of questions, and receiving such answers as the former cared to give. After some discussion, M. Guérin begged that his antagonist would prove to the Academy—1st. That we (the profession) know nothing whatever about the relation between vaccinia and variola. 2nd. That he himself did know something about it. M. Pasteur, who had probably not been listening to his colleague, replied that he had not understood a word, that he did not believe that anyone else had, but that if any member of the Academy could explain what had been meant he would be obliged to him. Here the venerable Professor Bouillaud intervened, and expressed the hope that the debate would not degenerate into a personal quarrel, but as soon as he had finished an angry discussion took place between the two previous speakers, which was rendered unintelligible by the cross-conversations of all the other Academicians. In the midst of this uproar the President was heard to exclaim that "the question appearing to have been sufficiently obscured, the meeting is adjourned," and so the sitting ended.

The *Journal Officiel* mentions the death of an old lady in Silesia, who appears to have been an authentic centenarian. Her name was Judith Singer, and she was born in 1768.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Sept. 30th:—

Hollies, George, Wellington, Salop.
O'Connor, Thomas, Ballina, Co. Mayo.
Pickthorn, Thomas Russel, Westbury-road, S. Kensington.
Shaw, John Alexander, Deal, Kent.
Tinoco, Francisco Esteran de, Bedford-place, Russell-square.

The following gentlemen also on the same day passed their Primary Professional Examination:—

George Locke and Charles William Grimes Burrows, Charing-cross Hospital; Robert Beswick and Lawrence W. K. Phillips, Guy's Hospital.

It is reported that a veteran journalist, M. Chauvet, has died in the hospital at Strasbourg from the effects of the bite of a poisonous fly.

GLANDERS is stated to be prevalent at Sutton Marsh, Lincolnshire. Six valuable horses have been slaughtered on one farm, and fears are entertained of the soundness of eight other animals.

A NEW method of preserving raw meat, discovered by Professor Artimini of Florence, and patented in this country, is said to be very effective. The material employed is stated to be less expensive than salt, and wholesome and pleasant to the taste.

ANOTHER death from the administration of carbolic acid in mistake for a black draught is reported. This time the accident occurred in Greenock Infirmary, and the unfortunate patient died within an hour of taking the poison. The nurse who administered the dose has been apprehended.

At the annual meeting of the Midland Medical Society the following gentlemen were elected to offices:— President: Thos. Savage, M.D., F.R.C.P. Treasurer: Mr. James Harmar. Hon. Secretaries: Messrs. John Garner and Henry Eales. Members of Council: Mr. T. H. Bartleet, Mr. John Greene, Dr. James Johnston, Mr. Furneaux Jordan, Mr. Wm. Thomas. Dr. J. Matthews Duncan has consented to deliver the inaugural address of the session, on the 20th instant, his subject being "The Treatment of Puerperal Fever."

CHESTER INFIRMARY.—On Wednesday last the Countess Grosvenor opened a new ward for children in the Chester Infirmary, in the erection of which the Duchess of Westminster had taken a great interest. Some 27 cots have been provided.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The first meeting of the session will be held at 1, Adam-street, Adelphi, on Friday, the 15th inst., at 7.30 p.m., when the President, Dr. J. S. Bristowe, will deliver an inaugural address.

KING'S COLLEGE, LONDON.—At the conclusion of Dr. Geo. Johnson's address the following distribution of prizes took place. Scholars: W. G. Evans, S. Farmer (*æq.*), senior; W. T. Brooks, second year; A. M. Vann, S. S. Merrifield, G. G. Hodgson, junior; G. G. Hodgson, C. P. Child, T. S. Short, Warneford, Class I; H. D. James, Warneford, Class 2; R. H. Botham, G. M. Taylor (*æq.*), Science (Clothworkers' Company); W. G. McMillan, Daniell.—*Winter Session, 1879-80.* Warneford Endowment: J. A. West, S. E. Craddock, prizes. Leathes Endowment: J. W. Kealy, P. H. Emerson, prizes. Anatomy: St. C. Thomson, prize; G. S. Aslett, A. R. Edwards, B. H. Stevens (*æq.*), certificates of honour. Physiology: R. G. Lynam, prize; H. R. Beevor, B. H. Stevens, certificates of honour. Chemistry: G. D. Porter, prize; R. G. Lynam, certificate of honour. Medicine: W. T. Maddison, prize; J. C. Castor, certificate of honour. Clinical Medicine: C. H. Whitcombe, prize; W. T. Maddison, certificate of honour. Surgery: S. Powell, prize; J. C. Castor, certificate of honour. Clinical Surgery (Professor Wood): S. Powell, E. H. Wagstaff (*æq.*), prizes. Clinical Surgery (Professor Lister): J. A. West, prize; St. C. Thomson, E. W. Benson, C. E. Goddard, certificates of honour. Zoology and Comparative Anatomy: J. F. Freeland, prize.—*Summer Session, 1880.* Practical Physiology: F. W. Le Maistre, N. H. Turner (*æq.*), prizes; T. S. Short, H. C. McDouall, certificates of honour. Practical Chemistry: H. C. McDouall, prize; G. Wale, J. F. Freeland, certificates of honour. Botany: C. W. Kieser, prize; T. S. Short, J. F. Freeland, certificates of honour. Tanner Prize: C. E. Goddard, prize. Todd Clinical Prize: S. Powell, prize. Pathological Anatomy: B. H. Stevens, prize; W. Groom, certificate of honour. Practical Biology: C. W. Kieser, prize; J. F. Freeland, P. G. Lewis, certificates of honour. Forensic Medicine: W. T. Maddison, prize; S. E. Craddock, certificate of honour. Obstetric Medicine: W. Groom, prize; A. H. Gordon, certificate of honour. Materia Medica: W. T. Brooks, prize; R. G. Lynam, S. S. Merrifield (*æq.*), certificates of honour. Clinical Medicine: P. Boobyer, prize.—*Associates:* W. H. Addison, C. E. Baddeley, R. Clarke, W. G. Evans, S. Farmer, T. W. Graves, H. J. R. Moberly, H. Morris, B. J. Newmarch, H. S. Parker, H. F. H. Smith, F. H. Spencer.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

BARLOW, J., M.D., M.R.C.S.E., has been appointed Professor of the Institutes of Medicine in Anderson's College, Glasgow.

BIRCH, R. C., M.R.C.S.E., L.R.C.P.L., has been appointed Medical Officer to the Children's Dispensary, Manchester, vice J. A. Mackenzie, M.B., resigned.

BLUMER, P., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the West District of the Bingham Union, Notts, vice A. Graham, L.R.C.P.Ed., resigned.

BOYD, S., M.B., B.Sc., M.R.C.S.E., has been appointed Surgical Registrar to University College Hospital, vice Silcock, resigned.

CAMERON, C. A., L.K.Q.C.P.L., F.R.C.S.I., has been appointed Public Analyst for Drumcondra Township. £10 10s. per annum.

CLARKE, A., M.R.C.S.E., has been appointed Medical Officer for the Fourth District of the Wells Union; also Medical Officer of Health to the Street Sanitary Authority, vice Paul, resigned.

COMPTON, T. T., M.B., C.M., has been appointed Junior Assistant Medical Officer to the Norfolk County Asylum.

FLETCHER, F. A. C., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Sutton District of the Keighley Union.

HAYWARD, W. H., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of No. 2 District of the Wolverhampton Union.

HILLS, A. P., M.R.C.S.E., has been appointed Surgeon to the London and Manchester Industrial Assurance Company (Limited), for the Battersea District, vice G. Hills, M.D., F.R.C.S.E., deceased.

HOWLETT, E. H., F.R.C.S.E., has been appointed Resident Surgical Officer at the Manchester Royal Infirmary, vice G. A. Wright.

MAY, B., B.Sc., F.R.C.S., has been unanimously elected to fill the newly-created honorary office of Casualty Surgeon to the Queen's Hospital, Birmingham.

NAPIER, A. D. L., M.D., C.M., has been appointed Certifying Factory Surgeon for Dunbar and District, vice Cowan, deceased.

NOURSE, W. J. C., L.S.A.L., has been appointed Medical Officer for the Bow and Colebrooke Districts of the Crediton Union.

OAKLEY, Mr. H. C., has been appointed Assistant Medical Officer at the Leeds Workhouse Infirmary.

PEARCE, A., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for the Salcombe Urban Sanitary District, Devonshire, for five years.

POGSON, W., F.R.C.S.Ed. &c., has been reappointed Medical Officer of Health for the Leeds Rural Sanitary District.

PRICE, R. G., L.R.C.P.Ed., L.F.P.S.G., has been appointed Medical Officer, Public Vaccinator, and Medical Officer of Health for the Ystradgynaf Union, vice Rhys, deceased.

READER, J., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Marshfield District of the Chipping Sodbury Union.

THOMPSON, J., M.D., F.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Abbotsham District of the Bideford Union.

TODD, M. S., L.R.C.S.I., has been appointed Medical Officer and Public Vaccinator for No. 3 District of the Abingdon Union.

TWEDDELL, G., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for the Houghton-le-Spring Urban Sanitary District, vice Lyon.

WANKLYN, Mr. J. A., has been reappointed Public Analyst for the Borough of Buckingham until September, 1881.

WATERSON, W. T., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Embleton District of the Alnwick Union.

YOUNG, A. G., M.B., B.Ch., has been appointed Medical Officer and Public Vaccinator for the Mountmorris Dispensary District of the Newry Union. Also Medical Officer of Health and Medical Attendant to the Royal Irish Constabulary at Mountmorris and Baleek, vice Pratt, deceased.

Births, Marriages, and Deaths.

BIRTHS.

BADCOCK.—On the 2nd inst., at Buckingham-place, Brighton, the wife of Lewis Carter Badcock, M.D., of a son.

GLYNN.—On the 28th ult., at Rodney-street, Liverpool, the wife of T. R. Glynn, Esq., M.D., of a daughter.

ILES.—On the 3rd inst., at Watford, the wife of Wilson Iles, M.D., of a daughter.

NORRIS.—On the 21st ult., at West Hoboken, New Jersey, U.S., the wife of Henry Lee Norris, M.D., of a daughter.

ROCHE.—On the 27th ult., at Ivan Lodge, Cavendish-road, Southsea, the wife of William Roche, Esq., Staff Surgeon, R.N., of a son.

TINKER.—On the 2nd inst., suddenly, at her residence, Talbot House, Southport, Mary, relict of the late Frederick Tinker, F.R.C.S.E., of Hyde, Cheshire, aged 63.

MARRIAGES.

COLVILL—CAREY.—On the 29th ult., at Arbroath, William Henry Colvill, Surgeon-Major, Indian Army, to Helen, daughter of the late Robert Carey.

DINGLE—HABGOOD.—On the 5th inst., at St. George's, Hanover-square, by the Rev. Thos. C. Webster, M.A., Vicar of St. Mark's, Old-street, W. A. Dingle, L.R.C.P.L., M.R.C.S.E., & L.S.A.L., of 61, Bunhill-row, Finsbury, E.C., late of the P. & O. S. N. Co.'s Service, to Fanny, third daughter of the late Robert Mace Habgood, Esq., of Upper Tooting. No cards.

THOMSON—SANDERSON.—On the 29th ult., at 21, Bridge-street, Musselburgh, by the Rev. Henry Moncrieff MacGill, Andrew D. R. Thomson, L.R.C.P.E., L.R.C.S.E., elder son of the late L. Ramsay Thomson, M.D., of Dalkeith, to Margaret Rimmer, only daughter of A. Macdonald Sanderson, F.R.C.S.E.

DEATHS.

BOWERBANK.—On the 5th inst., at Argyle-road, Castle-hill, Ealing, Lewis Quire Bowerbank, Esq., M.D., late of Jamaica.

BROWN.—On the 19th ult., at Haverfordwest, James David Brown, F.R.C.S.E.

MOORHOUSE.—On the 18th ult., at Ivy House, Ellesmere, James William Moorhouse, M.R.C.S.E. & L.R.C.P.E., aged 53.

SALOMON.—On the 30th ult., at his residence, Lund, Sweden, Ernst Carl Victor Salomon, M.D., F.R.C.S., and Knight of the Royal North Star, in his 49th year.

STRANG.—On the 28th August, at Turkasbad, near Queenstown, Cape Colony, Christopher Strang, M.B. & L.F.P.S.G., late of Workington, Cumberland, England, aged 32.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

EARLY RISING.

OF course the majority of the busy members of the community have been "away for change of air and scene," and, equally of course, the majority have derived substantial benefits—not at the moment apparent, perhaps, but to be evidenced, in better health or more energy, presently. This is, therefore, a good time to speak of such reforms in the management of self as may be expedient. We venture to suggest that those who have not yet made a fair trial of the practice of early rising should do so. With a cup of tea, and perhaps a single slice of bread-and-butter, to wake him at 6 or 6.30 in the morning, a fairly healthy man may go to his study, and enjoy the priceless luxury of two or three hours of work, when his brain is clear, and the distractions of the day's ordinary business have not begun to assail him. The practitioner of an applied science, such as medicine, is especially in need of time for reading and quiet thought. In the active hours of the day this is denied him. At night he is, or ought to be—but for the bad habit of reading by night, probably formed in student days,—too weary in mind and body to do good work. In the early morning, with his brain recuperated by sleep, and his whole system rested, he is especially fit for labour. Those who do not feel thus on awaking are either the subjects of some morbid state, or the slaves of a habit which, however common, is essentially unnatural. Some of the difficulties which beset the task of early rising are due to want of method in the act of "getting up." It is comparatively easy to rouse oneself instantly, but to not a few of us it is extremely irksome, and almost impracticable, to rise slowly—that is, taking time to think about it. The man who *really* wishes to rise early should get up the instant he wakes, and, if weakly or over forty years of age, instead of plunging into cold water or applying cold to the head to rouse himself, he should, as we have said, take a cup of tea or milk to stimulate the organism before expecting to elicit a reaction by a powerful depressant such as the cold bath or douche! Many persons make a mistake in this matter, and by taking their bath immediately after getting out of bed lower the vitality instead of raising it. In certain cases it is better to leave the bath until after a walk or a spell of work has thoroughly awakened the organism and called out its energies. Experiences in relation to this and other matters must differ as widely as constitutional peculiarities diverge; but, speaking generally, the early morning is the time for serious work, and those who do not so use it find a poor substitute, and one which is by no means hygienic, in the late hours forced upon them. A man cannot get up early if he goes to bed late; but as between the two extremities of the day, the morning is, on all accounts, the best for brain exercise.

Mr. Harrison, (Ellesmere).—The notice will appear next week.

"A QUESTION OF TREATMENT."

To the Editor of THE LANCET.

SIR,—Your correspondent, "J. B. C.," refers to an obscure eruption on the tongue, accompanied with acne pustulosa. After using soothing applications for the acne (it would be better to omit the iodide of potassium in the mixture spoken of, as it would probably be increased by the use of this drug), the best application to the tongue would be: After carefully drying the surface, and holding the tip in the hand, previously covered with a towel, to cautiously paint the patch over with a little strong nitric acid, keeping the tongue protruded for a few minutes. The eruption appears from the diagnosis to be psoriac. A couple of applications done about four days apart will suffice.

Yours truly,

Sackville-street, Oct. 4th, 1880.

JAMES STARTIN.

CRAMP WHEN BATHING.

A CORRESPONDENT writes:—"Being accustomed at the seaside to swim out far, and remain in the water for periods approaching an hour, I have been sometimes visited with fear of cramp. Farther than, on one or two occasions in my life, having had the slightest symptom in the water of a cramp in the calf of the leg, I have never had any experience of such a seizure so fatal to the swimmer. I am sure the information would be interesting and useful to many besides myself if you could inform me through your columns what state of body, stomach, or circulation renders one liable to such a disaster." The question raised is interesting and important. Is the so-called "bather's cramp" true cramp?

Burnley.—The question should be addressed to a practitioner privately.

"LIFE AND MIND ON THE BASIS OF MODERN MEDICINE."

To the Editor of THE LANCET.

SIR,—My attention has been called to a review in THE LANCET of Sept. 25th of my late tract, "Life and Mind on the Basis of Modern Medicine." Perhaps, as the subject seems at present a burning question of the day—a problem agitated in all quarters of the civilised world by all classes of thinkers, from archbishops downwards, and as its solution lies more in the province of scientific medicine than elsewhere,—you will have the courtesy to give me this opportunity of making a very few brief remarks in your valuable pages in deprecation of your strictures. I have endeavoured so steer clear of what you term "irrational dogmatism," and to base my conclusions on well-established data of modern science and philosophy, medical as well as physical, conscious as I am that neither caution, reflection, nor experience, theoretical or practical, has been spared in their elaboration. All I have at heart to prove is the simple, seemingly unassailable thesis that in matter itself, organic or inorganic, there is *unity* of substance, and that no dual factor of a non-material, spiritual, or animistic character is required for the performance of function, the necessary energy for which residing, as an immanent property, in matter or tissue itself. In other words, that there is no such reality as vital or motor principle—only vital or motor force or function—the corpuscular *vis insita*. Originally the title of my essay was "Life and Mind on the Basis of Materialism" (Hylozoism); but the term "Modern Medicine" was substituted on its latest reissue, in deference to the claims of the latter to the proud distinction of being the science of human nature itself.

Absolute atheism (see thesis 8, page 32) forms no part of my argument. All it contends for is the non-interference of "spirit" in any shape, "great or small," in cosmical phenomena or in cerebration, from which latter alone all conceptions and perceptions, so far as knowable, originate. Properly interpreted, my contention is the most self-evident and undeniable of truisms, either in the light of ordinary common sense or in that of contemporary science and philosophy. I aim at nothing beyond a clear enunciation of the data at the root of all modern science since Newton's Principia—data never more accentuated than in the canons of modern medicine since the origin of Histology at the commencement of the nineteenth century.

Your obedient servant,

ROBT. LEWINS, M.D.,

Army and Navy Club, Sept. 30th, 1880.

Surgeon-Major, H.P.

* * We maintain that the non-existence of a something beyond or behind matter cannot, with our present knowledge, be proved. The statement that function or motor force is immanent in matter is not sufficient, in these days of rigid analysis, as an explanation of the meaning of energy in organised bodies, present in the state called life, and absent in death. Co-ordinated or associated action surely has a higher or deeper signification than can be predicated of corpuscular *vis insita*. This can never account for the intelligent co-operation of atoms in working out harmoniously the well-being of the individual organism.—ED. L.

A Twenty Years' Subscriber.—There are certain special provisions for practitioners admitted to the M.R.C.P. examination. Our correspondent would have no difficulty in obtaining the diploma as he proposes. Bristowe's Principles and Practice of Medicine and Niemeyer's work are both valuable for study. Special treatises, such as Murchison on Diseases of the Liver, and Walshe on Diseases of the Lungs, may also be read with advantage.

A QUESTION IN PHARMACY.

To the Editor of THE LANCET.

SIR,—I should be glad if any of your readers would kindly give me a formula for the preparation of a subcutaneous solution of morphia which will keep without depositing any of its salt.

Yours obediently,

Oct. 4th, 1880.

L. K. Q. C. P., &c.

M.D.—It does not follow that because it is desirable to abolish the Apothecaries' Companies, it is wise to attempt to abolish the Royal Colleges, or that it would be possible to do away with all qualifications but the degrees of the University of London. This is an unpractical suggestion.

A Surgeon's Assistant.—There are wards set apart for paying patients at St. Thomas's and University College Hospitals. Application should be made to the Secretaries.

DUPLICATE MEDICAL DEATH CERTIFICATES.

Judex.—A registered medical practitioner, should he see fit, is at liberty to issue any number of duplicates of a medical certificate of the cause of death of a deceased patient. It is also true that the relative of a deceased person who hands over to any other person than the local registrar the medical certificate of the cause of death is liable to a fine; the fine, however, is 40s., and not £10. After a medical practitioner has, however, once issued a medical certificate, it is very undesirable that a second should be issued differing from that first given, unless under very exceptional circumstances. We are unable to see any reason, however, for consulting the local registrar as to the expediency of issuing any number of *duplicates* of medical certificates.

J. P.—Dr. James Beddoe, F.R.S., is President of the Health Section at the meeting of the Social Science Congress now being held in Edinburgh.

CASE OF POPLITEAL ANEURISM.

To the Editor of THE LANCET.

SIR,—I send you an account of a case of popliteal aneurism, the manner of cure of which ought to be recorded.

On December 30th, 1878, Mrs. —, aged sixty-nine, of middle height, rather stout and strong woman, went to see a neighbour's pig killed, and, when standing by, an old man tumbled up against and over her, knocking her down forwards on her face and knees. She felt something give way in her right knee, and from this time had great pain shooting down her leg "like a bad gathering." I saw her a week after, and, from her description of the pain and accident, I suspected aneurism, and on examination found a pulsating swelling at the lower part of the popliteal space, with all the characteristics of aneurism, but the bruit not well marked. The muscles of the leg (outside particularly) were also a good deal strained. I ordered lead lotion and complete rest; but she would not even keep her leg up, and I could not make her understand that the case was a serious one. Four weeks after this, as the aneurism was getting larger and the pain severe, I persuaded her to flex the knee as much as possible at night when in bed, and keep the leg up in the daytime. In a week the pulsation was perceptibly less, the pain very much less, and the tumour smaller. At the end of three weeks the pain was almost gone, and the aneurism hardly to be felt at all—in fact, had almost disappeared. At this time she took liberties, walking about &c., and the tumour became larger and more painful, but felt hard, as if a good deal of deposit had taken place. I cautioned her that she might have to undergo a serious operation, besides suffering great pain, if not more careful, after which she behaved better, and the tumour gradually subsided, there being no sign of it on May 10th, 1879. The only treatment carried out (and that only partially) in this case was flexing the knee at night when in bed. The cure was complete, and the woman has been well ever since.

Yours faithfully,

Rhymney, Sept. 9th, 1880.

T. H. REDWOOD, M.A., M.D., &c.

A Poor Assistant.—It is not clear to us that a practitioner advertising for an assistant should pay travelling expenses of applicants. Where would be his protection? Supposing twenty applied, he might have to pay an inconvenient sum. Where the distance is considerable, there should be an understanding about travelling expenses.

Mr. R. T. A. O'Callaghan.—There is a Medical Defence Association, of which Mr. George Brown, 12, Colebrooke-row, Islington, is the Honorary Secretary.

SINGULAR FREAK OF AN EPIDEMIC OF SCARLET FEVER

To the Editor of THE LANCET.

SIR,—Scarlet fever, having broken out in a distant parish of my district, has exhibited a freak hitherto unobserved by me in any former outbreak of such sporadic disease. After having invaded two families, four children in one, and five children and the mother in the other, occupying cottages some distance apart, it appeared in a house in which, remotely located from the other points of its assault, it attacked two more children, aged respectively two and four years. It should be noted that in all the twelve cases the disease was of a most virulent type, concentrating its force upon the throat; and just as these were emerging from the attack under the treatment adopted, three older children succumbed to diphtheria in a marked form—one, a girl of twelve, exhibiting a tubular diphtheritic stratum adherent to the fauces and pharynx, and in this case and that of the brother of ten years, the throats, when cured of the disease, showed deep and extensive ulcerations, causing the tissues of the walls and pillars of the fauces and velum palati to trail in shreds on the base of the tongue, plainly due to the ravages of the bygone frightful malady. These ulcerations are now almost healed. Although I had known scarlet fever degenerate or tail off, as it were, into diphtheria, I had never before seen it appear in its original phase, as in the present outbreak, in two other families in the same village, and that in the space of a month. Surely this singular alternation of the diseases, coupled with the fact that both are alike amenable to the same treatment, furnishes a strong argument in favour, if not of identity, of the close affinity of the diseases. Of the twelve cases of scarlet fever and the three of diphtheria above alluded to, though most severe, not one has had a fatal termination, most having thoroughly recovered, and the others rapidly approaching recovery.

Yours faithfully,

Crick, August 17th, 1880.

T. OSBORNE WALKER.

Dr. H. Collins.—Our correspondent should apply to one of the licensing bodies for information concerning any special classical works required to be read for the preliminary examinations, and as to the other subjects he might consult some scholastic friend.

"LEGALISED QUACKERY AND LOW CHARGES":
ANOTHER DEFENCE.

To the Editor of THE LANCET.

SIR,—Will you allow me to draw attention to a misprint in the letter of mine which you published last week? I wrote, cod-liver oil, which costs a little over one halfpenny per ounce, you printed 1s. 2d., or twenty-eight times the real cost. A serious misstatement like that is apt to throw discredit on my figures.

I should also, in further elucidation of my statements, wish to make the following additions:—That I believe there are no doubt practices where the cost of the drugs would exceed 1d. per bottle; but in these the drugs are not only chosen for their remedial properties, but also for the elegance of their preparations. The only object I had in my letter was to point out that medical practitioners do not realise the fact that drugs are not expensive articles of commerce, with few exceptions. I would therefore as a further test suggest, that the cost of drugs in large colliery and ironworks practices, supplied to mixed patients, men, women, and children, should be computed. In such practices, though the medical officer acted with perfect *bona fides*, the more elegant preparations would be excluded—for example, compound tincture of cardamoms and aromatic spirits of ammonia. A certain disturbing influence is also to be taken into consideration in computing the cost of drugs in hospital out-patients. The physicians and surgeons there, no doubt legitimately, avail themselves of the opportunity of testing the value of new and expensive drugs, not because they are convinced of their efficacy, but because they wish to watch their effect. I have no doubt that the younger and more enthusiastic members of the hospital staff are more expensive prescribers; while, lastly, some men retain a lifelong bias in favour of complicated prescriptions, others again favour the simplest combinations. All I wish to point out and to maintain is that drugs, if given to large numbers of patients, are not so expensive as is generally imagined, and even if they were twice the price which I indicated, my argument would hold good.

Your obedient servant,

M.D. Lond.

London, Oct. 4th, 1880.

AN ILLUSTRATION OF THE SYSTEM OF CHEAP
DISPENSARIES.

To the Editor of THE LANCET.

SIR,—I have noticed the insertion in your valuable journal of numerous letters in defence of a system of supplying medicines and advice on terms which to the run of medical men seem derogatory to the dignity of the profession, and scarcely consistent with advantage to the poorer classes. Admitting your fairness in giving a hearing to those whose style of practice is so condemned, I confidently rely on your giving insertion to the following illustration of cheap medical practice which lately occurred to me:—

I was asked a few weeks ago to see a man said to be suffering from spasm of the heart, and to be very bad. I went, and found a middle-aged man in great distress and pain between his disease and the diagnosis which had been arrived at a cheap private dispensary in the neighbourhood. I think the diagnosis had quite as much to do with his condition as the disease, if not more. I found he had been going to this dispensary for a week; that he had paid only one shilling for several visits and medicine; that he had never seen the principal, but his assistant, who is, I should charitably conclude, unqualified, and that the assistant had said that the disease was in the heart. Here he was, after a week of such treatment, in a state of mingled shock and extreme pain, chiefly in the cardiac region. The pulse was "slow," but regular, and the heart-sounds normal. Hot flannels and turpentine had been applied diligently. I was told, too, there were some spots on the side. I immediately suspected and soon found a very brilliant semicircular eruption of herpes zoster, and was enabled to assure my stricken patient that he had no heart disease, and that his pain was due to an eruption, which, however painful, was not deadly or dangerous. The pain, however, was unmistakably bad, and quinine, ammonia, local applications of laudanum, and the internal administration of it, with a second visit to the patient's house, were all necessary on that first day.

For curiosity's sake I asked the chemist who dispenses my drugs to give me a memorandum of what he was going to charge me for the medicines supplied to this patient on that one day—viz., an ammonia mixture, twelve pills with two grains of quinine in each, ointment of oxide of zinc, laudanum for outward use (the zinc not being effective), and an opiate draught. The bill was three shillings for one day's medicines, to say nothing of two visits and my time. Three shillings! and our cheap doctors are to give three weeks' medicines and advice for the sum that I am to pay the chemist alone for one day's medicine! I leave your readers to judge. But I have not done with the absurdity and, I must add, injustice of cheap doctoring in this case. I have to add that the patient never saw the principal, only the assistant, who was so little up to his work that, though he saw the crop of shingles, he did not diagnose it, but diagnosed a grave fault of the heart, which did not exist. It is this kind of slopwork that the shilling a week system favours, and the profession will look to you for a judgment upon it.

I am, Sir, your obedient servant,

London, October, 1880.

M.D

VIVISECTION.

DR. WILDER, of the Cornell University, proposes to classify vivisection into "sentisection," experiments attended with pain, and "callisection," those which are painless. He thinks that callisection is necessary for even elementary physiological instruction; but sentisection should be "the unwelcome prerogative of the very few whose natural and acquired powers of body and mind qualify them above others to determine what experiments should be done, to perform them properly, and to wisely interpret the results. Such men, deserving alike of the highest honour and the deepest pity, should exercise their solemn office not only unrestrained by law, but upheld by the general sentiment of the profession and the public."

Traveller might suggest to some of the practitioners resident in the locality the expediency of taking the matter up.

PLACENTA PRÆVIA AND RUPTURE OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—As I am not aware of having read or heard of a case of placenta prævia in which rupture of the uterus took place, the following facts may be of interest to some of your readers:—

On the 16th instant I was summoned to attend Ann C—, the wife of a "heckler" at Parrmill Threadworks, who was stated to be in labour, and in a dying condition from hæmorrhage. On my arrival the woman had been dead for more than an hour. I made a vaginal examination, and found the os uteri well dilated; but instead of the presenting part of the child, my finger impinged against a soft spongy mass, which I at once surmised to be the placenta, and, on introducing my hand into the uterus, I felt the placenta adherent round the cervix, except at the left side, where it had apparently separated during the labour. I could not find the fetus in the uterus; but on introducing my hand still further I felt it distinctly in the abdominal cavity. The woman who attended stated that the patient had been in labour for four hours, and had several "red discharges"; but ultimately an alarming flooding ensued, and at the same time the patient complained of severe pain in her abdomen, and became faint, and mentioned that she was dying.

I made a post-mortem examination about five hours afterwards. On opening the abdomen, a considerable quantity of blood was found in the cavity of the peritoneum. No evidence of peritonitis could be detected. There was a large rent on the anterior surface of the uterus, running, from above downwards and to the right. The edges of the laceration were uneven, and the muscular tissue of the organ was considerably thinned at these parts, but did not appear to present any marks of disease. There was no injury of any of the adjoining viscera.

From what I could learn of the patient's history, she was forty-two years of age, and had previously given birth to fourteen children, the last two being still-born, and she had always been a strong and apparently healthy woman.

Your obedient servant,

Beith, Ayrshire, Sept. 17th, 1880. C. R. MACDONALD, M.B., C.M.

A Critical Reader.—We believe the uniform fee for evidence at an inquest is a guinea, an extra guinea being given for a post-mortem examination. Adjournment of the inquest does not entitle to a further fee.

"CHANGE AS A MENTAL RESTORATIVE."

To the Editor of THE LANCET.

SIR,—Would your correspondent, Mr. Downes, follow up his excellent suggestion contained in your last issue by naming some suitable works. I have for some time past been very desirous of engaging in such study.

Yours obediently,

October 4th, 1880.

M.D.

CHLORAL AND MORPHIA.

To the Editor of THE LANCET.

SIR,—Your issue of Sept. 25th contains a letter from Mr. De la Motte, setting forth the supposed fatal influence produced on the system by the combined internal administration of chloral and morphia. The case of Mr. Amplett is quoted as an example.

Mr. De la Motte appears to me to have arrived at a somewhat hasty conclusion. At least personal experience teaches me differently; and from what I have read of Mr. Amplett's case, death was the result of an overdose of chloral (200 grains), and not to the combination of chloral and morphia.

On two separate occasions I have taken chloral and morphia, following one another within one hour, for the relief of neuralgia and in order to obtain sleep. On the first occasion I took at bedtime twenty-five grains of chloral; but this not having produced the desired effect, within forty-five minutes I followed it with twenty minims of liq. morph. hydrochlor. In a very short time sleep was induced. I awoke the following morning without experiencing any unfavourable after-effects, and quite free from neuralgia. On the second occasion I followed up a similar dose of chloral with an opium pill of one grain. A state of calmness and almost freedom from pain resulted, but without sleep. Again, I felt no evil effects the following morning.

My object in sending you these few short notes is that possibly it may induce some of your readers to publish their experience on this important subject.

I remain, Sir, yours truly,

Maidstone, Sept. 30th, 1880. CHARLES BOYCE, M.B. Edin.

VACCINATION IN GREECE.

A CORRESPONDENT asked a few days ago for information on this subject. By the courtesy of the Consul-General for Greece we are enabled to state that vaccination is not compulsory in that country, but the operation is generally practised, and there are doctors in every commune who are bound to vaccinate the poor gratis.

B. L.—The carbolic acid may be used *pure*, provided care is taken not to let it touch the mouth.

INFANT DIARRHŒA.

To the Editor of THE LANCET.

SIR,—In every practice the above disease must be now prevalent, and, as I have had great success by a certain mode of treatment, I think it my duty to mention it, so that my brethren may be led to give it a trial. In typical cases, where frequent stools have led to constant vomiting and collapse, the method has succeeded when bismuth-with-chalk and nearly all the stronger astringents, both vegetable and mineral, have failed. The treatment is, I believe, old enough; but it is certainly not generally adopted, and this is my excuse for troubling you with this letter. For a child a year old prescribe the following:—Opium powder, one grain; subchloride of mercury, three grains; white sugar, twenty-four grains. Mix well, and divide into twelve powders. Order one to be placed on the tongue every three hours, and watch the effect. Carefully and particularly insist that for twelve hours the child is to have no other medicine, and no food except teaspoonfuls of water, barley-water, or weak brandy-and-water. In a great many cases it will be found that three or four powders will arrest both sickness and purging. The powders must then be given at longer intervals, and milk administered cautiously and in increasing quantities. I have tried opiates in the liquid form without effect. For a child as young as two months, half a powder may be given every three hours with safety. The abstinence from food proper for several hours is a most essential part of the treatment.

I am, Sir, yours &c.,

Middlesbrough, Sept. 23rd, 1880.

S. WALKER, M.R.C.S. Eng.

Madras Retired.—Our correspondent has been very unlucky; but as there has been no breach of faith or departure from the Regulation, we do not think it would serve any useful purpose to publish his letter.—We have received G. I., U. S. Club, a communication with the same signature, which shall have consideration next week.

A HARELIP TROCAR AND TUBE.

To the Editor of THE LANCET.

SIR,—In your issue of this day, there is a description (page 539) of a little instrument "contrived by Surgeon-Major E. Ambrose Fitzgerald." I enclose you an instrument of a precisely similar character, which has been, with some others of the same pattern, lying in my needle-box for the last four years! I cannot give you any history of it, except that it came to me with some other things on the decease of a relative (a surgeon) in the year 1876, and that the silver tube was then as black with age as a portion of it now remains. I have cleaned part of the tube to ascertain its composition, as I was not aware before reading Mr. Fitzgerald's description that it was silver.

You have considered the instrument worthy of notice in your journal. Perhaps you will also insert this note. When Mr. Fitzgerald reads it, he may offer some further information by way of explanation.

Your obedient servant,

F. ROYSTON FAIRBANK, M.D.,

Doncaster, Oct. 2nd, 1880.

Surgeon to the Doncaster Infirmary.

To the Editor of THE LANCET.

SIR,—In this day's issue of THE LANCET you describe a harelip trocar and tube contrived by Surgeon-Major E. Ambrose Fitzgerald, Bengal Medical Service. This instrument is not a new invention, having been in use many years. I cannot say who invented it, but can speak in high terms of its efficacy, having used it on several occasions.

I am, Sir, yours faithfully,

N. MAYNE,

Longford, Oct. 2nd, 1880.

Surgeon to the Longford Infirmary.

A Constant Reader, (Dublin).—The German Pharmacopœia (ed. 1874) gives directions for preparing tinct. colocynthidis as follows:—One part of powdered colocynth macerated in ten parts of rectified spirit until a clear yellow liquid is obtained.

THE USE OF PURE WATER IN ERECTING BUILDINGS.

To the Editor of THE LANCET.

SIR,—In reading your remarks upon the prosecution of the builders who used earth in the place of mortar at Edmonton, it occurred to me to mention how important it is to use pure water in mixing mortar, whether for building or for plastering dwelling-houses. Newly-built houses are notoriously apt to prove anything but salubrious to the first inmates. Much of this unhealthiness of new houses may be owing to the use of foul and polluted water for making the mortar.

I am, Sir, yours truly,

Marlborough College, Sept. 26th, 1880.

WALTER FERGUS, M.D.

Mr. Richard R. W. Oram.—The conduct alluded to is most inexplicable and unusual. Under the circumstances, our correspondent's duty is to claim a fee from the husband of the lady. Clearly he cannot regard his services as given to a brother practitioner who does not recognise either him or them.

An Address ON ELEMENTAL PATHOLOGY,

*Delivered in the Pathological Section of the British
Medical Association,*

By SIR JAMES PAGET,
PRESIDENT OF THE SECTION.

EVERY pathologist must have felt that the greatest difficulty in his study is in the manifold complexity of the body in which it is pursued. The living human body is, surely, the most complex mass of matter in the known world. In composition it surpasses the highest powers of chemical analysis; in mechanism it is as far beyond the calculations of the physicist; its structures are but dimly seen with even the most perfect microscope; all the known forces of nature are constantly and coincidentally at work within it; through circulating blood and a nervous system every part is within swift communication with all the rest; and it includes the apparatus of a mind from whose influence no portion of its matter is distantly removed. And in this body the pathologist has to study, not that which is fixed, orderly, and natural, but that which is in disorder and unsettled. May we not therefore hold that, among all the sciences of observation, human pathology has, in the very nature of its subject-matter, the greatest difficulties to contend with?

I have long and often felt that in these difficulties we might gain help from studying the consequences of injury and disease in the structures of plants. For although these, too, are complex, minute, and hard to analyse, yet they are less so than are the structures of any but the very lowest animals; and, which is most important, the processes in them are not subject to the influence of a nervous system, or of a common nutritive fluid distributed from a central organ and quickly carrying to every part materials derived from all the rest. In the absence of a nervous system and of a quickly circulating nutritive fluid, we come nearer to the opportunity of studying a really elemental pathology, nearer to the changes wrought between formed and varying formless matter. I say, without a nervous system and without a circulating fluid; for though some of the properties of vegetable structures, such as are shown in their subjection to the influence of anaesthetics, their movements in relation to light, and the various groupings of their colouring particles, indicate a likeness to the properties of simple nervous structures; and though, through communicating minutest channels, every portion of a plant may be regarded as in relation with all the rest, yet these small degrees of likeness can scarcely detract from the great contrast between plants and animals in the having and the not having nervous systems and circulating bloods.

It was in the hope of promoting a study of elemental pathology that I determined, when I had the honour of being asked to preside in this Section, to put together various facts in vegetable pathology which, in the idleness of vacations, I had learned. I thought that I might provoke some of my hearers to a study which I supposed that few had pursued. I was nearly turned from my purpose when I found the vast quantity of good scientific work that has been done in it; the many volumes of books and the hundreds of papers relating to the injuries and diseases of plants which have been written within the last twenty years by both botanists and cultivators, especially by those engaged in the schools of forestry and orchard-culture in Germany. I saw no hope of studying them worthily; but, in those that I have had time to read, I have seen enough to make me more than ever sure that human pathologists may find, in watching the consequences of injuries and diseases of plants, facts of the highest interest in their more proper study.

Let me point out some few of these; but, first, I must disclaim all pretence of an ability to treat the subject as a scientific botanist, or a practical gardener, or anything intermediate between these excellent extremes. I can only, as a human pathologist, see that knowledge of great value is within our reach: I may be able to point out to you where and how some of it may be found; and I can promise attrac-

tions of novelty in the study, and of renown to be gained from it; for, admirable as is the work already published, very little of it has been done by those who could fully estimate its value in human pathology.

In my selection of subjects, I will limit myself to those that are of interest in general pathology; and, first, to hypertrophies, or the simple overgrowths of natural, or nearly natural, structures. Of these, I do not know that there are in plants any well-marked instances corresponding with those which are the most frequent in animals, in which a part grows in direct proportion to the exercise of its function, and thus may grow to relative excess when its function is, through the will or for necessary adjustment, excessively discharged. But, in plants, there are abundant opportunities of studying those forms of hypertrophy which depend on an increased supply of nutritive material to any part. To mention but one: the arts of partial or complete "ringing" and of constricting or bending the branches of trees depend for success on their ensuring an accumulation of nutritive sap in the part of the branch from which its movement is checked. The result is what we may call a hypertrophy of flowers or, in other instances, of fruit, or wood, or bark, proportionate to the increased supply of nutriment; just as, in ourselves, hairs and some other structures will grow excessively with an excessive afflux of blood; or, still more and in almost exact parallel, as limbs will grow with a retarded reflux of lymph.

Similarly, I believe that you may find in plants many instances of the kind of hypertrophy which, in ourselves, we call compensatory, in that, one part being repressed or removed, another enlarges with growth of natural structures, as if for compensation; for I think that some of the arts of gardening are based on observations that removal of certain parts of plants will induce an overgrowth of others. Perhaps, among these you may find facts which may help to explain those obscure cases in animals and ourselves in which parts or organs, which have no natural alliance in function, are yet commonly allied in disease, as if they were in some relation of complementary nutrition. Such are the excessive growths of connective tissue and fat which may follow the removal of the generative organs; events well known but, I believe, not well explained.

I will not cite more facts. Only consider how many of the luxuries from our orchards and gardens are really such growths as in our pathology we should call hypertrophies, and that to produce these is within the art of the gardener, and you may see how large a collection of facts which may be useful in our study are within our reach, constantly at hand for observation and, which is yet more important, within the range of experiment.

Let me speak next of some illustrations of the simple defects of nutrition, which we class as atrophies or degenerations.

I am not sure whether there be among plants any atrophies by mere wasting of parts once completely formed, which may be compared with the emaciation of animal structures.¹ Shrivelling, drying, withering, and defective growth are only too frequent; but these are all different from that unmaking and removing of structures which we trace in both the healthy and the morbid processes of nutrition in animals.

The atrophies with degeneration are very numerous; but I will take for illustration only that group which we may see beginning all around us in the decay and fall of leaves. This decay is their senile degeneration. It is marked chiefly by their changes of colour—the changes to which we owe the characteristic beauties of our autumn scenery. These are accompanied by changes of texture, shown in the dryness and brittleness of the leaves, and by changes of chemical composition; but I will refer to only the changes of colour, and observe that these indicate decay, not death. They do not occur when fresh leaves are quickly killed, as in hot water, or when they are pressed and dried for an herbarium.

Among many things to be observed in the changes of colour, let me first ask you to note their usual symmetry. One of the characteristics of mere degenerations, as we see

¹ I may have overlooked many instances of it; but some that may seem like mere wasting are rather diseases with associated degeneration. Such are the gum-disease (gummosis), the resin-flux (resinosis), and others of the same group, which I find classed as liquefactive diseases, and in which cell-walls, wood, and other structures dissolve in or into morbid products. See Srauer, *Handb. der Pflanzenkrankheiten*, p. 184; and Frank, *Encycl. der Naturwissenschaften, Pflanzenkrankheiten*, p. 369. I venture to guess that these may give help in the study of our mucoid and other liquefactive degenerations.

them in old age, is that they are symmetrical. I hardly need cite instances; many of us may study them in ourselves or one another. Symmetrically we become, equally on right and on left, bald, or grey, or wrinkled, or dusky with dark pigment in our epidermis, and harsh-skinned with thickening and hardening of its cells. And we know that, as a rule, arteries become symmetrically fatty and calcareous; and that very commonly joints are symmetrically affected with the arthritis of old age, and so on. Now, similarly, the rule in leaves is that, in so far as they are symmetrical in shape and structure, so are the changes of colour which mark their decay or degeneration.² You may find, indeed, very many exceptions to the rule; for it cannot be observed in leaves which have been unequally expanded, or whose several parts have not been equally exposed to heat and light, or in which parts have been killed or injured. Many accidents may hinder the observance of a rule of symmetry; but the observance cannot be an accident; and, if you will pick up leaves enough, and look well at them, you will see that the general rule of symmetry in the changes of decay is as evident as is the similar rule in our own symmetrical diseases and degenerations.

The changes may best be seen in those leaves or leaflets of dicotyledons which have a simple bilateral symmetry, a median vein, or fibro-vascular bundle, passing through the length of each leaf and giving off side-branches; but it is often scarcely less plain in palmate and in pinnate leaves, both in their several divisions and in the comparison of each division with its opposite fellow. In such leaves you may trace, in each pair of similar parts, similar changes of tint spreading uniformly or gradually over them; usually, first from a darker to a paler green, from brighter to less bright; then to pale yellow or brown, or to some tinge of red, or scarlet, or flame-colour, or some other of the tints that make autumn scenery glorious.

Now let me point out some things in our pathology which these facts may illustrate. The changes of colour are not mere chemical changes ensuing in a dead part. Leaves do not usually die till after, sometimes long after, they have fallen. Their changes of colour and of texture, even to the last dull brown in which they crackle as we tread on them, are vital changes in the same sense as are those which we see in ourselves in the advance of old age. In this view they may be taken in evidence on the question as to the nature and meaning of some symmetrical diseases.

There are at least two reasonable theories concerning these diseases. One is, that the symmetry is due to the relation between some morbid material in the blood and certain parts which are symmetrically placed, and are exactly identical in composition; absolutely like to one another, and not absolutely like to any other part which is not similarly affected by the same material in the blood. This was the theory on which Dr. William Budd and myself wrote our essays on the symmetry of disease nearly forty years ago. The other, which at that time I only ventured to suggest, but which is now, I think, rather dominant, is that symmetry in disease is determined by the disturbed condition of symmetrically disturbed nerves, the disturbance issuing from a single nervous centre. I cannot now discuss this question, or endeavour to show how probable it is that each theory is true and sufficient for certain cases, and that for some time they must be combined; but the symmetry of decay in leaves may be taken as a strong fact in support of at least these two principles: 1. That symmetrical changes may occur in degeneration and disease, as certainly as in development, without any influence of a nervous system or of a circulating blood; and 2. That, among structures which, to all our tests, may appear identical, those alone may be absolutely alike which are symmetrically placed. Surely no two things can appear more alike than are two adjoining leaves of a tree, or two parts of the same leaf; and yet, if under the same conditions, these do not decay in the same time and measure, it can only be because they are not absolutely alike. Thus the symmetry of decay in leaves may prove that none but symmetrically placed parts may be verily alike; and thus the possibility, to say the least, that in ourselves a diseased blood may similarly affect only such parts, and thus that, among symmetrical diseases, there may be some of which the essential and sole necessary condition is some morbid material in the blood.³

But let me now point out another of the lessons which may be read in the decaying leaves; for really the pathologist may find in them as many as the moralist and the poet have found.

The leaves, I have said, are decaying, not dead; and their fall is due to other degenerative yet truly vital changes. Dead leaves do not similarly fall. If a branch have been killed before autumn, you may often see its dead leaves hanging dry and withered all the winter through; and often when leaves are yellow and withered in their last decay, they hang quivering and spinning, ready to fall, yet waiting. Each leaf is literally hanging on a thread, and at last, by a rougher wind, or a drop of rain, or some chance violence, the thread is broken, and the leaf falls.

This breaking of the thread is preceded by degenerative changes in the structures of the leaf-stalk and of the stem adjacent to their juncture or articulation. These changes were first well described by the late Dr. Inman⁴ of Liverpool; they have since been made more fully known by von Mohl⁵ and others, and the rules observed in them hold, with certain variations, in the fall of petals, bracts, fruits, some twigs, and other deciduous organs.

In their beginning and maturity, the structures of the leaf-stalk and the stem or twig are continuous. There may be some external mark of distinction, but within there is exact continuity; the epidermis, parenchyma-cells, fibres, and sap-vessels are alike continuous. But, in preparation for the fall, changes ensue in the adjacent parts of both leaf-stalk and stem. In both, alike and equally, the cells multiply by partition, and those most nearly adjacent change, by a process of degeneration, into cork-cells, dry, brown and air-holding. Then, as these degenerative changes advance from opposite directions towards the plane of junction between leaf and stem, they meet, and, at their place of meeting, an intermediate layer, or rather two layers, of cells die and become scale-like and part asunder; and now the leaf is ready to fall. It hangs only on the dried thread of fibres and vessels which pass into it from the stem, and the stem is protected by its layers of cork and withered cells from the invasion of parasites and insects.

It would be hard to find a more admirable instance of processes adjacent, coincident, concurrent to a common end, yet independent. We have many of the kind in our pathology, but none more evident, or more within reach of complete study, as of vital processes tending to one end, but not guided from one centre; concurrent, but not concatenate; as independent as are the works of the several bees that make one honeycomb. And thus we may learn from the falling leaves a lesson against thinking that, when we see concurrent morbid processes, we must always expect to find some centre from which all are guided. It is not to be doubted that in organisms such as ours, in which the work is more divided according to its kind, and more distributed to appropriate organs, more is subjected to regulation by central organs, and the working of each part is more influenced by that of all the rest; yet it is not probable that, in any instance, the law is abrogated according to which each elemental structure lives its own life in a method determined by its own inherent properties. There is no law in pathology more important than this: let the falling leaves remind us of it.

And yet one lesson more. That thread on which for a time the falling leaf hangs quivering—that thin bundle of fibres and vessels connecting it with the stem—is regarded as a development from simpler cell-structures. Fibres and vessels are “higher” structures, so much higher that the relation between the Vasculares and Cellulares in plants may match in importance with that between the vertebrata and the invertebrata in animals. But mark this instance of anomaly in our language. In the elevation from the lowly cellular state to the higher dignity of fibres and vessels, there is, indeed, an instance of that development which makes fit for membership in a higher economy—that is, an economy more nearly like our own. But in the attaining of this fitness there is loss of vital power. There is no such activity of organic life in the vessels and fibres of wood or

perfect symmetry of colours is observed; in others, as in many laurels, complete asymmetry. Instances of completely unilateral decay may sometimes be found in cabbage-leaves and turnip-leaves near the roots; sometimes, also, in laurel-leaves. They may be suggestive in the study of unilateral organic diseases, some of which are not wholly due to disturbances of trophic nerve-force.

⁴ Henfrey's Botanical Gazette, 1849, p. 59, from the Proceedings of the Literary and Philosophical Society of Liverpool, No. 4, p. 89.

⁵ Botanische Zeitung, 1860, Jahr. 18.

² “In so far,” for the symmetry of living things is not mathematical; it is artistic, in the divine perfection of art.

³ In connexion with this subject, it may be useful to study the variations of leaves, in some of which, as in many varieties of Begonia, a

bark as there is in the cells around them; they are comparatively unchanging; they cannot multiply; they cannot repair their own injuries; cannot protect themselves; cannot even degenerate as the fading leaf-substance around them does (for even to degenerate needs vital power); they can only die, and the dead thread on which the decaying leaf hangs cannot dispart itself; it must be broken by some alien force. In the taking of higher form the cells seem to have spent their power of forming.

Now we have in ourselves similar instances of degenerations which we call developments. When cartilage becomes bone we usually say it is developed; but this is only because it becomes fitter for a share in a higher condition of our economy. The man is "higher" than the child, and therefore we are ready to speak of everything as ennobled if it contributes to his manliness. But, in respect of texture and self-activity in vital process—in the activity which can work with even a distant supply of blood,—cartilage is better than bone; and the change into bone partakes of the nature of a calcareous degeneration; in general utility there is development, in self-activity there is degeneration.

The same may be said of many changes from cells to fibrous structures in ourselves. In teleology there is elevation; in vital histology, degradation. And this anomaly of words is found, not without some confusion of thought, in parts of our pathology. We speak of rickets as a hindered or arrested development, and so, in respect of purpose and utility, it is; but in respect of elemental tissue-life it is rather an arrested degeneracy.

You may study such anomalies of terms in many instances in plants. Let me suggest a thesis for the D.Sc. There are such things as green roses: show the analogies between a green rose and a rickety child.⁶

But now let me end my notices of those changes in plants which you may study for illustration of atrophies and degenerations and retrogressive metamorphoses in ourselves. There are many more, such as the sweetening of fruits, in which, while becoming more useful to ourselves, they acquire chemical conditions less distant from inorganic matter; and the red and yellow tints of ripeness, which are colours indicative of imperfection, or the central softening and decay of fruits very like that of large morbid growths. In all these, as well as in decaying leaves, you may study general pathology when and where you will.

I will next speak of the repair of injuries. In studying the processes of repair in plants a first observation may be that, speaking generally, the repair of injuries and diseases is less complete in them than it is in animals, even than in ourselves and others of the highest groups. The processes of repair, so far as they extend, are similar in both, but in plants they rarely extend further than to be defensive or protective to the injured parts; they seldom reach to what may justly be called reparative or reformative, and much more rarely to anything that may be named reproduction or regeneration of lost parts. Indeed, the only instances of reproduction which I have found recorded are those of the cells of *Vaucheria*,⁷ and of parts of the minute leaflets of the small moss, *Bryum Billardieri*, and even in these the mid-rib was not reproduced.⁸

In most of the ordinary wounds and other injuries of leaves and stems, as well as of petals and fruits, we see only incomplete repair. Punctures and incisions and minute excisions, such as in ourselves would be quickly closed and healed, and in a few days be almost unobserved, are, in plants, not closed at all, unless with careful help and in some few species.⁹ The gaps or spaces are not filled-in with new material, there is no tendency to contraction, the edges do not draw together. The healing which does take place in these cases may be compared most nearly with that which, in animals, we see in wounds left open and healing under a scab. The cells and the ends of the fibro-vascular bundles which are cut across empty themselves and die, and then, becoming dry they slowly scale off and are detached; or the contents of the cells may ooze out and yield a gummy deposit, which may dry and glaze the surface of the wound. After a time this cracks, and is detached; but while it

lasts it serves, as do the dead and dry layers of divided cells, for some protection of the cut surfaces. They serve, alike, for timely protection against invasion by parasites, just as in an animal do the dried blood or the first exudation on a wound left open. Beneath this temporary protective layer the more permanently protective or reparative changes now ensue, and these are usually described as in two methods—the formation of cork and the formation of callus.

In the healing with cork, which is the more frequent in the more succulent parts of plants, the layers of cells next beneath the dead cells or the gummy covering multiply by frequent partition, forming rows of thin-walled flattened cells. Then of these the outermost, lying at and next to the surface of the wound, become cork-cells, their walls thickening and their contents being replaced by air. The more deeply seated remain active, still capable of multiplying and of replacing the cork layer, which now serves as a dermal covering, and becomes continuous with the periderm at the borders of the wound, but does not acquire an epiderm.

In the healing with callus, examples of which may be studied in the closure of the wounded surfaces of slips and cuttings, the living cells next to the surface of the wound grow out into papillæ or short pouches, with or without cell-division. These may form a protective cork-layer, and if they approach from nearly adjacent surfaces they may intermingle and unite; or they may form other structures, replacing those injured, as epithelial cells, parenchyma-cells, or a new cambium layer, in which bark and wood and fibro-vascular bundles may form.

The best instances of healing after this manner are in the wounds or the splittings or strippings of bark which do not go through the outer layers of the cambium in vigorously growing stems or branches.¹⁰ In the actively living structures of the cambium, if it be very gently guarded, callus forms by outgrowth and division of cells, somewhat after the manner of granulations, and of these, not only bark but wood, vessels, bark and cork may form and become connected with the similar tissues at the borders of the wound.

These, I say, are examples of the best healing known in plant-structures, and they must be worth studying carefully, for they would illustrate many points in our own healings and are far more apt for minute examination than any injured structures in animals.¹¹ Yet even in these the defective reparative power in plants is shown. An animal, if skin be stripped from it, will, if possible, lick the raw part, and then let dust and air and dirt collect and help to make a scab with blood and oozing fluid, and under the scab new skin will form, not indeed perfectly but well. But when bark is stripped only down to the living cambium the raw part must not be touched; mere wiping or touching with the finger, or too much drying, may kill the cambium-cells and prevent all healing; or parasites may attack it and make more mischief. And when we leave these best cases the repairs observed in plants are far less; even small branches or twigs when partially broken do not reunite, unless in a few instances in succulent plants in which the broken surfaces are carefully kept in contact, and even in them no new woody tissue may be formed. You know what is called in surgery a greenstick-fracture and its sure method of repair. In a real green stick no repair of the kind would happen; no ensheathing or intermediate callus would form; at the best the broken surfaces would be covered with a protective layer of cork without an epiderm. I cannot find an instance of repair in plants which even approaches in completeness to the ordinary repair of a broken bone or a divided nerve or tendon in ourselves or any other animal.

Perhaps the strongest contrasts may be seen in the wounds or strippings of trees that go down to the layers of wood; or, in what will follow the amputation of a branch from a tree and of a limb from a man. You may see in front of St. Catherine's College some elms from which branches were cut yesterday, and not far off, at Addenbrooke's Hospital, I dare say you may see patients from whom parts of limbs have been amputated; and, if the stumps have been treated after the manner advised by our distinguished President,

⁶ Help may be found in the study of Dr. Ord's thoughtful paper "On Brownian Movements" in the Journ. Micros. Soc., June, 1879.

⁷ As quoted from Huxtein by Frank in the Encycl. der Naturwissenschaften, Abth. i. Lief 12, p. 380; and in Botan. Zeitung, 1878.

⁸ Described by K. Müller in Botan. Zeitung, 1856, p. 200, and quoted by Frank, Waldenburg, Beijerinck, and many more, who do not add any similar fact.

⁹ See Frank, l.c., p. 383-4.

¹⁰ It may be well studied in longitudinal wounds made through bark for the relief of tension. (See H. de Vries in Archives Néerlandaises, t. xi; Haarlem, 1876.)

¹¹ I have adopted, chiefly, the descriptions of healing given by Frank (l.c.). I hope that more minute descriptions and more mutual illustrations between animal and vegetable repairs will soon be published by Mr. Shattock, who has been studying the subject with great care and skill.

they will have been left to be repaired by nature as truly as are the stumps of the branches of the elms. The stumps in the hospital have been cut in better shape for healing; but those in the garden have the advantage of more perfect rest, and, in whatever shape they might have been cut, the result would have been the same. Now, it is most probable, nearly sure, that the human stumps will be healed in a few weeks, and that in two or three months all the wounded parts will be covered in, with skin and scar and cuticle firmly adhering and compact. But it will need a very long life to see the healing of any stump of the same size on the trees. The wood cut across will die, and its necrosis will never be repaired; rotting, like a caries, may extend from it into the trunk, but it will not be repaired. Year after year the annually formed rings of new wood and bark will overlap the borders of the wound; each year they will grow thicker and will converge, and at last after many years they may, perhaps, meet and coalesce and cover in the wounded surface; but they will not unite with it, there will always be a cavity over the dead wood: a stump so ill-healed as would be a shame to any hospital. I must not imply that there are no better healings after amputations in trees than you may see in elms; some trees heal better, as do beeches and planes; but I think it may be said generally that the stump of any branch will need more years for its healing than the stump of a limb of the same size will need of weeks; and that, in the end, the work of the weeks will be far more reparative than that of the years. And in this reckoning I would include not only the limbs that have been surgically cared for, but those that have been violently crushed or mutilated in animals left to themselves.

This slowness and defect of repair are observed in other things besides the healing of wounds. Dead portions of leaves, or of wood, or other structures, are not cast-off unless by external force.¹² We have borrowed the word "exfoliation" to tell of the separation of dead bone; but, as I have said, it is only living leaves that can exfoliate. Dead pieces of young wood remain where they were killed, as they often are, without external wounds, by hailstones¹³ or any accidental blows. The structures adjoining them may become hard or corky, but they do not separate from them, there are none of the reparative changes which are seen in even a "quiet necrosis." Similarly you may often see dead tips of leaves, perfectly defined from the living parts by colour and by texture, yet without any groove or other sign of process of separation, the dead and the living epidermis remaining still continues. And as to recovery from diseases I believe it may be summed up in saying that no vegetable structure altered by disease ever reverts to its original healthy state.¹⁴

Now let me commend to you this subject of the repair of injuries in plants, not only for illustrations of our pathology, but as a part of the study of what may be called the philosophy of healing. They heal very slowly and imperfectly; they may need many years for the healing of small injuries—eight or nine years for a frost-crack in a young branch—¹⁵ yet they do heal; the intention, as Hunter would have called it, is not given up. Let me relate one case.¹⁶ A fir tree, fifty years old, had a large piece of bark stripped from its trunk. The wound extended round nearly a fourth of the circumference of the trunk, and laid bare the wood. It was not dressed or guarded; the outer layer of the exposed wood died as usual, and then every year the successive annular growths of new wood and bark extended a little further over the bared place. In one hundred and fifty years these growths met and coalesced, and the wound was covered in. When the tree was felled and cut through at the injured part, where there was still a deeply depressed scar, the concentric rings of wood proved the growth of fifty years before, and one hundred and fifty after, the injury, and even now the healing was not complete; there was still a cavity between the old wood and the new. The healing was not such as we should call good in any similar case in an animal. Still, there was healing; the "intention" was maintained for a century and a half.

Surely, in our familiarity with the processes of repair we overlook their wonder; the wonder that there should be in anything an inherent power of repairing the consequences of accident; that, for instance, in any one of us, after living for many years, with only those timely regular changes, the methods of which we have inherited from our ancestors, an accident, some quite unlikely event, such as may never have happened to an ancestor, such as no conceivable process of selection or of inheritance can have prepared us for, some mere chance as we must call it, should bring-out an increased power and a new method of organising structures exactly adapted to the repair of the consequences of that chance. And let me remind you that this power of repair is not a property of living things alone—it is evident in crystals.

It may seem unreasonable to say that we may study principles of elemental pathology in the apathetic inorganic world, or in things that we call dead. But certainly we may study them in crystals. The experiments of Jordan which I repeated many years ago, and related in lectures at the College of Surgeons¹⁷ have been extended by Pasteur,¹⁸ Karl von Hauer,¹⁹ and others, and this chief fact has been abundantly proved—that if a portion of a crystal be broken off, or filed or dissolved away, and if then the mutilated crystal be replaced in a solution of the same salt or of an isomorphous one, the lost part will be replaced, the damaged form will be repaired. In this process of repair the whole crystal will be enlarged, new crystalline matter will be formed on every surface, but the quantity formed on the injured part will be greater than that formed on any other part, and repair will be more active than mere growth till the proper form of the crystal is regained. Then, when the repair is complete, growth alone will go on and each part of the crystal, if it remain in the same solution, will increase in due proportion with the rest.

It seems impossible, by any just definition, to separate this process from those which, as pathologists, we study in the repair of the accidental injuries of living bodies. In all alike, when a natural form has been lost or impaired by external force, the native formative power works at the injured part with an energy and a method modified appropriately to the recovery from the loss, and then, when the recovery is achieved, returns to its previous energy and method. Of all alike, it may be said that where we find evidence of a design to be fulfilled in the attainment or maintenance of a certain form, there, also, we may find evidence of some power to repair injuries which that form may sustain from accidental external forces.²⁰ However various in its degree and method the power of repair is in all.

I wish that some of you, with a good broad knowledge of pathology, would study this repair of crystals and the possibility of their recovery from other changes besides those of form. The study could hardly fail to yield facts that would be very useful in the proper business of our lives. Only let me warn you that, as I have learned from Mr. Maskelyne, injured crystals need great care; if they are to be well repaired they must have as gentle handling and as kindly nursing as the tenderest patients of our own race.²¹

Even if, in studying the repair of injured crystals, we should not learn things directly useful in our own pathology, yet the facts should keep us safe from the error of referring reparative processes to such supposed causes as are called increased action, or determination, or reflex trophic force, or the like; they must convince us that repair is the result of some elemental general law of formed matter prevailing beyond the whole range of life and living structure, even in all natural bodies having harmonious form and proportions.

But while in the widest survey of repair that we can take, we may thus see an instance of so simple an expression of the Divine Will as we call a general law, yet in the degrees of apparent observance of that law, we find differences very wide and, so far as I know, quite inexplicable. We do not find equality of reparative power in all formed bodies, nor any rule of proportion between that power and their less

¹² A partial exception must be made for the tips of the fibres and vessels divided in some cuttings. See Arloing, *Sur le Bouturage des Cactées*, Ann. des Sc. Naturelles; Botanique, B. iv. p. 24, 1876.

¹³ Goethe, *Ueber den Krebs der Apfelbäume*, 1877, p. 2.

¹⁹ Sitzungsbericht der K. Akad. der Wissenschaften, B. xxxix; Wien, 1868, p. 611.

²⁰ In the repair of crystals, it is well seen that form, rather than size or other quality, is the highest object of the reparative process. Karl von Hauer has found that if a portion of a crystal be so removed that all the parts of the remaining mass are still within the law of its primary form, the repair is either very slow or is even not attempted.

²¹ Yet their healing may be "left to nature." Mr. Maskelyne has often seen in native crystals marks of injuries repaired.

r more simplicity of structure. There are some rules of such proportion among animals, but they are very partial, and the rule fails completely when we compare the reparative processes in plants with those in animals.

Let me revert to this comparative defect of healing powers in plants, though it may be only to tell my ignorance of all relations between it and any other of their properties or the conditions of their life. It is not related to any immunity from injuries enjoyed by them, for they are far more exposed to injuries than are animals; nor to any absence of necessity for healing, for, after wounds, they suffer severely, and often fatally, from the attacks of parasites of all kinds. It is not because of any lack of productive power at the injured part, such as we might be disposed to refer to the want of circulating blood or of nerve-force; for from many wounds of plants, as the art of grafting and of multiplying by slips or cuttings may show, entire new plants may grow; and yet these are not reproductions; they may, in one sense, replace that from which the slip was cut away, but they do not reproduce it; they are not continuous with its remains, and they commonly become much more than that which was lost would have become. Again, the increased growths, which injuries may produce in plants are not to their own advantage, though they may be so to that of a successor or a parasite; and on many wounds of wood hard and heaped-up masses of new wood may form, such as may be roughly compared with our cheloid scars and excesses of bone-callus. Neither can the defective repair be ascribed to any general tenacity in the regular methods of growth in plants, or to any general want of pliancy or of ability to adjust themselves to new conditions; for the art of horticulture abounds in instances of changes in methods of growth completely adjusted to changes of condition. There are in plants ample powers for enlarged growth and ample range of pliancy in method; but that special change in method of growth, which is familiar to us in ourselves and other animals, and which, as with design and on purpose, is adapted to the speedy healing of injuries, is in them comparatively defective. Which of you will work so as to find the explanation of what seems so strange an inconsistency?

(To be continued.)

ABSTRACT OF A

Lecture ON THE

DESIGN AND SCOPE OF LECTURES ON THE PRACTICE OF MEDICINE,

Introductory to that Course given at Westminster Hospital,

By OCTAVIUS STURGES, M.D., F.R.C.P.,

JOINT LECTURER ON MEDICINE.

GENTLEMEN,—The lecturer on medicine in the present day has unusual difficulties to encounter. Most that he has to say is already written in books. There are the seventeen volumes of Ziemssen's Cyclopædia, each as big as a family bible, and together weighing half a hundredweight and too bulky to take in a cab, and there is the vade-mecum which may be easily carried in the pocket. With so wide a range of choice, the student can learn just as much, or as little, as suits his purpose, at his own time, and in his own manner. What, then, is the justification for systematic lectures, especially when it is considered that we have in addition a teacher of practical medicine to demonstrate the methods of physical diagnosis, and a medical tutor to direct the pupil's study and test his knowledge? The lecturer on medicine, thus hedged in on all sides, must confine himself strictly to the terms of his undertaking—to the formal discussion, that is to say, of the various diseases of nosologists in a regular order. What is the use of it?

The question is one which is never absent from my mind at this season. Every student gives a practical answer to it by the regularity, and still more by the manner, of his attendance. We, on our side, all of us, it may be presumed, satisfied that our labour is not in vain, are probably not altogether at one as to its proper place and object. Some will

say, for example, that by this oral teaching, which is more enduring than the silence of print, the lecturer conveys to his hearers, not a mere transcript of the books, but an enlarged view of the subject derived from long experience and a wider reading than the student can procure for himself. But there is the obvious reply, that this comprehensive treatment of the subject, like all the rest, soon gets into print, and is to be found in the books. When a teacher, by felicity of language or description, or any other unusual gift, succeeds in imparting knowledge more clearly or compendiously than heretofore, the whole world is soon in possession of it. The case of the lecturer is thus continually getting worse, for he has to contend with the ever-increasing force and ability of that which is written.

And yet, I cannot but think, more and more with every year, that there is a service in these lectures which nothing else can supply. Granted that what we have to say is already better said in books, granted that what is curiously called the "practical" part of the subject is now taken out of our hands, yet still, as I believe, there remains a purpose to be fulfilled by the occupant of this chair which becomes the more pressing as the subjects for medical study multiply. I will endeavour, in as few words as possible, to make this appear.

It is often said of medicine that it is becoming every day more precise in its language and more scientific in its methods; and if the ground of the improvement be sought, it will be found to depend in large measure upon the fact that the various appliances of more exact sciences have been pressed into its service. It is not that we have become more shrewd in observation or more logical in inference, but that we get more help from without. Accordingly, much time must now be spent in learning the use of instruments and the application of physical and chemical tests. And it happens inevitably that the student, observing the exactness and penetration of these aids and their close connexion with medical progress, learns to despise the vagueness of old medicine, and to regard this preliminary and manual part of his work as though there were nothing beyond. It is the function of these lectures to show him how greatly he is mistaken in this belief, to point out all that yet remains beyond the view of his instruments, and to make him understand how much higher than any manipulative skill or application of physical science is that faculty of judgment and discrimination which has yet to come, and cannot be learnt by rote, or by any other means than actual contact with disease. It is customary, I know, to speak of the results of such contact in very general terms, as though by association with the sick some mysterious virtue kept flowing, which, under the name of experience, should give to every man, from the mere efflux of time, a capacity in proportion to his years. I have no such meaning. On the contrary, I believe that accuracy in observation if not practised early is not practised at all, and that "experience" often comes to mean no more than the habit of superficial examination. What I would imply is that the time of your career has now been reached when you can no longer be guided solely by the strict letter of printed instructions—when you must either become the servants of routine, or else begin to exercise higher powers of intellect than have hitherto been appealed to.

The course of medical education is, in fact, always the same, but all do not pursue it to the end. There is, first, the recognition of the separate phenomena of disease—that period of training when isolated signs and sounds are much insisted on and discussed, as though they possessed an intrinsic and independent value. Next comes the faculty to appreciate these signs aright, as acquiring significance in their several combinations. Lastly, and in varying measure as the great acquisition of all, comes the capacity to interpret, not physical conditions merely, but all that these imply in their various relationships. That these are, in fact, the several stages of the journey may be known by the numbers that are to be found resting at each. Some pass their whole lives content with bare words; others go no further than to determine the physical conditions of disease, leaving or guessing the rest; only a proportion gather the facts together and press them home, perceiving that their task is incomplete until the whole of the phenomena have been reviewed and arranged.

And what I would have you observe of this progress is the danger that besets the passage from a lower and routine learning—which nevertheless is seen to be the most exact and the most directly informing—to that higher knowledge which, while it employs the best powers of the mind, is not

of the same certain and assured value, or to be appraised and measured with the same facility, as the other. It is this sense of insecurity that makes so many halt at this point, rehearsing for ever their tables and formularies, dealing in the jargon which they mistake for learning, and decline to exchange for it.

Here then, I repeat, is a definite object to be aimed at in lectures upon medicine: the actual exhibition and demonstration of disease, in all its complexity and variety, by means of living illustrations—exercise under a master in the very same problems which must presently be solved alone, with that sort of help to the solution which comes from the possession and the study of “worked examples.” We need fear now no competition of the books, for we know that ours are better. I know for myself with what personal satisfaction, after labouring to describe some morbid sound or other aspect of disease difficult to reach by words, I have led the puzzled listener to the thing itself. Whatever is best in the verbal description gets thus fixed indelibly, while every such diversion is for the student a fresh contribution to that aggregate of experience which is to determine in the future, other things being equal, his relative merit amongst his fellows.

Such teaching must, indeed, always be incomplete, inasmuch as it depends for its illustrations upon the actual material that we have at hand. We cannot, like the books, discourse with the same fluency of hydrophobia and the plague, as of acute rheumatism or pneumonia. Yet the main purpose is not the heaping up of facts, but rather practice in arranging and interpreting them, and even this incompleteness of illustration is not without its use, for it gives the student a correct view of disease in its true perspective, exposing the unreality of that dead level of official description where every affection is depicted in its turn as though all were equally distinct and well defined.

You will say, perhaps, that by this treatment the course of lectures in medicine becomes a course of clinical lectures. And so truly does it, yet not in such manner as to interfere with the lectures we now call clinical. These latter are occasional and unconnected, they deal with some particular case, and point out unusual features of disease. They are controversial and speculative. Systematic lectures, on the contrary (in the strictest sense *clinical* if they are to be of any use whatever), follow a definite course, from which they only diverge occasionally, when attracted by the nature of their material; they point out not so much the exceptions of disease as its common rule, and show in the flesh in a series of living pictures all the chief articles of the syllabus.

All this implies, no doubt, much more than sitting at a lecture. The education I am thinking of is not to be got sitting or by any passive attitude whatever. The only question is as to the precise co-operation of teacher and learner in what must be a common work. Such difference of opinion as exists upon this point is partly explained and justified by considering that different orders of mind need different training. I cannot doubt that some have worked out this practical knowledge for themselves painfully and laboriously at the bedside, and have obtained their reward at last in a greater acumen and facility of diagnosis than often comes to those who give the hand and are shown the way. Yet for the great majority it is not too much to assume that our guidance and suggestion must go for something, provided only that the spirit of our teaching tends to educate and exercise the pupil's own judgment, not to bind him down to anybody's gospel. And while I am persuaded that no just conception of medicine can ever be conveyed in a series of dogmas, I have no fear whatever lest the frank exposition of the subject in all its ambiguity and incompleteness should disturb the proper relation between master and scholar. On the contrary, there comes to this latter of necessity, by the operation of the more liberal training, a conviction which both maintains the authority of the teacher, and in due season will form the ground of the student's own self-confidence—the conviction, I mean, that so long as the methods pursued are right and thorough, time and use continually make the way plainer and lessen the probability of error.

Such, then, is the ideal of that medical training which it is the chief business of these lectures to help forward. I am far from supposing that it is altogether realised. There is, indeed, a short reply to all that I have been trying to say, which I hear from you so often and with such little variation, that I cannot but think there is some substance in it. You say that there is no time for this sort of teaching, and

no need for it; that the student can pass his examination without it. It is not easy to say whether the irony of such a statement is the more bitter as it concerns our present system of medical education or the vigilance of our examining bodies: the importance we attach to that practical knowledge which is the grand aim and end of all medical study, or the pains we take that only those who possess such knowledge shall have authority to take charge of the sick.

CASES OF ANEURISM ILLUSTRATING DIFFICULTY IN DIAGNOSIS, AND THE USE OF ESMARCH'S BANDAGE.¹

By WALTER RIVINGTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL.

THE two following cases of aneurism in the lower limb present features worthy of notice. The first case was one of idiopathic aneurism of the anterior tibial artery—a rare affection, and attended in this instance with conditions which invested it with more than usual interest. Being of large size it raised a suspicion that it might be malignant disease, and having been originally mistaken, before it came under my care, for an abscess, and incised, it became the seat of secondary hæmorrhage, which, owing to the misguided refusal of the patient to submit to the necessary treatment, led indirectly to a fatal issue. The only means at my disposal for arresting the hæmorrhage, whilst giving the patient a chance of cure, was Esmarch's bandage, and it will be seen that, after one application for an hour without result, a second application for an hour and a quarter on the following day, when the hæmorrhage occurred, produced the desired coagulation in the tumour. This success, however, was itself unsuccessful, for the force of the arterial circulation was reduced below the point needed to return the blood through the already obstructed veins, and gangrene of the foot ensued. Amputation was persistently declined, and death resulted. The following is the outline of the case:—

CASE 1.—Arthur W—, aged fifty-eight, of rather a spare habit, was admitted into the London Hospital on the 8th February, 1877. His family history was very good, and he had always been a strong, able-bodied working man. He had been at sea for many years as a butcher, and for the last nine years had been a common labourer in London. He had always been a regular, temperate man. There was neither history nor appearance of syphilis, and the only severe illness which he had experienced was one attack of intermittent fever. He had never suffered from rheumatism, or been troubled with his leg. About six weeks before admission (the day before Christmas), whilst walking up stairs he felt a pain in his right leg, just below the knee, and on looking at it, he found a swelling not larger round than a halfpenny, and the same night he felt it pulsating under his fingers. Four days later he had medical advice, and was told that the swelling was an abscess. He was recommended to poultice it, and this he continued to do for about four weeks. The swelling enlarged rapidly every day, and the whole leg became larger and more painful. Two days before admission a small aperture was made in the tumour. The bleeding was free, and, according to the patient's description, “the blood spurted up in a stream like a fountain.” A compress and bandage were immediately put on, and the bleeding was checked.

The patient was advised to come to the hospital, and he did so two days later. There was then a large oval swelling commencing a few inches below the right knee, and with the long axis corresponding to the axis of the limb. It looked red and inflamed, and on palpation gave a feeling of semi-fluctuation. Over the centre of the swelling there was a small punctured wound which was closed and partly healed. On pressing the scab off a few drops of pus exuded. The house-surgeon introduced an exploring needle through the aperture, and blood came trickling along the groove. Being

¹ A paper read before the Hunterian Society.

doubtful about the nature of the case, he sent the patient to bed to await my examination.

When I saw the patient in the ward, the aspect of the tumour at once suggested an aneurism. On pressing with the ends of my fingers firmly on the tumour, a strong pulsation was communicated to them, and examination with the stethoscope revealed a loud bruit of a rather rasping character. The swelling had more of a bruised than an inflamed appearance, but the skin was hotter than that of the opposite limb. The swelling extended round the outside of the leg to the posterior aspect; the calf bulged and pulsated. Large glands were found in the groin. Pressure with fingers on the calf communicated an impulse to fingers placed over the tumour in front. Compression of the femoral arrested the bruit and pulsation. Over the tumour, and especially behind, large veins were seen ramifying. The foot was a little swollen, and the tibial arteries beat feebly. The only question in my mind was this, Is the tumour an aneurism or a pulsating cancer?—a question to which I deferred giving a decided answer; but on this point I was clear, that the case should at once be treated as an aneurism by means of compression, the effects of compression to be carefully watched, and action taken according to circumstances. Hence I directed that the patient should be brought down from the upper ward, where he was lying, to the accident ward, where he could be under the immediate eye of the house-surgeon, and that a tourniquet should be applied without delay.

The following day it was found that the effect of the compression which had been kept up through the night had been to diminish the impulse in the swelling. Some comparative measurements of the two limbs were made by Mr. Buxton, the dresser, with the following results:—The circumference 2 in. below the head of the fibula in the sound limb was 10 in., and in the diseased limb 12; at 3 in. distance, 10 and 14; at 4 and 5, 10½ and 15; at 6, 9½ and 14½; at 7, 9 and 13½; at 8, 8 and 12½; at 9, 7½ and 11½; and at 10, 7 in. and 10½ respectively.

The patient was seen early on Saturday, the 10th, by two of my senior colleagues. Both inclined to the view that the tumour was of a malignant nature; one agreed with me that, in the existing uncertainty, it was desirable to continue treating the case as aneurismal by means of compression, holding amputation in reserve; and the other gave a decided opinion in favour of early amputation. A third colleague saw the case, and balanced the points on both sides very carefully without committing himself to a pronounced conclusion.

I mention these details to show the difficulty that often exists in cases of aneurism of coming to a correct diagnosis. In favour of malignant tumour were the size of the swelling, the enlarged glands in the groin, and the dilated veins over the tumour. The chief objections to the view of malignancy were, that the tumour could not be traced into connexion either with the fibula or with the tibia, and the character of the bruit. The bruit was loud and rough, audible along the tibia, over the knee-joint and internal malleolus. At one point—viz., the upper part of the anterior aspect of the swelling—Dr. Turner noticed that the bruit was double. I determined, therefore, to continue compression till Monday, if nothing should arise meanwhile to demand interference. In case of hæmorrhage, which seemed not improbable, owing to the artificial opening on the face of the tumour, there would have been no difficulty in temporarily arresting it with the tourniquet or Esmarch's elastic tube, and I gave directions that the patient should be constantly attended.

On Sunday I found that the swelling had increased in size, measuring an inch more in the centre than on the previous day, notwithstanding the application of the tourniquet. The pressure of the instrument gave the patient considerable discomfort, but this was relieved by hypodermic injections of morphia. On Sunday afternoon I determined to try the effect of the application of Esmarch's bandage, and I adjusted it in the way recommended by Mr. Wagstaffe, passing it quite lightly over the tumour, and firmly above it, as far as the middle of the thigh, where it was pinned. Cotton-wool was placed over the foot and leg before the application of the bandage. The bruit and pulsation were arrested for one hour, and at the end of that time the bandage was removed, after screwing up the tourniquet. After awhile I loosened the tourniquet gradually, and in a few minutes pulsation became evident, and both it and the bruit were re-established as markedly as before. The tourniquet was reapplied, kept on all night, and not removed till the middle of the following day. About one o'clock the clot plugging

the aperture into the aneurism gave way and severe hæmorrhage came on, bursting through the cotton-wool and bandage round the limb. The bleeding was arrested by the tourniquet. I was summoned to the patient. I was about to adjust Esmarch's bandage with the strap for temporary security against hæmorrhage and to ascertain its effect upon the tumour, and I was about to urge upon the patient the necessity of leaving our hands unfettered in regard to amputation, when the patient informed me that he would not submit to any operation. The hæmorrhage had diminished the tension of the swelling, and so far altered it as to convince me that it was a false aneurism and not a malignant tumour. The only measure which the patient would tolerate was compression, but compression, whether digital or instrumental, with the ordinary tourniquet was ineffectual, and could not be maintained continuously so as to preserve the patient from the danger of recurrence of hæmorrhage. The only resources left were Esmarch's bandage and injection of perchloride of iron, or a combination of the two. I preferred Esmarch alone, and placed the patient under chloroform during its adjustment. Mr. Hutchinson, whose visiting day it was, saw the patient while the strap was on, and exerted his persuasive powers in vain to induce him to leave the surgeon unfettered. At the end of an hour and twenty minutes the bandage was removed, digital compression being maintained for some time longer. The limb was placed in cotton-wool. Pulsation had not wholly ceased in the aneurism after the removal of the elastic tube, and the circulation promised to become re-established in the leg and foot. But when coagulation in the sac became complete, and all pulsation and murmur were abolished, it was found that whilst the heel became hotter than usual, and showed marked evidence of the opening of a collateral circulation, the anterior part of the foot and the toes were cold. The veins on the dorsum became distended, and the surface mottled. On the following day the toes were cold and had lost sensation. Amputation was again urged without success. The tumour gave exit to venous blood, and became much diminished in size. Day by day the gangrene advanced. On the fourth day after arrest of the pulsation the disorganisation had extended to the leg. The orifice of the aneurism now began to ulcerate, and to give exit to black blood and broken-down clot. In spite of the pain and the danger to his life, the patient adhered with a Turkish fanaticism to his resolution not to part with his limb. On the 19th a line of demarcation had become evident in the lower third of the leg, but the constitutional state of the patient had become serious; quick pulse, high temperature, basi-pneumonia, flushed and anxious face, anorexia, want of rest and delirium, and in a few days more the scene was closed. Towards the end he might have been persuaded to submit to amputation, but it was too late for recovery, and I did not press him further.

Locally the post-mortem examination disclosed a nearly complete solution of continuity of the anterior tibial artery, and its ruptured part was occupied by a sac composed of the surrounding tissues and blood-clot. The sac was filled with broken-down coagulum. The aneurism was situated a few inches from the origin of the artery, and this portion contained a clot of partially decolorised fibrin, and the clot extended into the popliteal artery. It was by no means clear that the decolorised portion of the clot, which occupied the popliteal artery, had not formed at the time that the blood coagulated in the sac.

The second case was one of aneurism of the popliteal artery, projecting not in the popliteal space, but on the inner side of the limb, and thus inviting the unsuspecting practitioner to mistake it for some other tumour. The notes of the case yield the following history:—

CASE 2.—Henry C—, forty-four, a soldier, a well-nourished man, height 5 ft. 9 in., was admitted into the London Hospital under my care on August 20th, 1879, suffering from a tumour occupying the lower part of the inner side of the left thigh. He had served in the Crimean war and the Indian Mutiny. In 1858 he had a sore on the penis, which was followed by sore-throat, but not by rash, loss of hair, or other recognised sequelæ of primary syphilis. He had been accustomed to march fifteen miles a day for several weeks together. He had never had rheumatism or gout. In 1864 he had fever in India, and in 1872 he suffered from jaundice. He was discharged from the army in 1874, and since that time he had been a clerk. In the early part of last June he began to suffer from pains of a darting character in the left ham, aggravated at night when he was warm in bed. Fourteen days later he noticed on the inner

side of the left ham a small lump, which was painful, and gradually got larger and more painful. At times when he was out walking it would become so painful that he would have to stop and raise his leg, and this always relieved the pain. He consulted a hospital surgeon. Scott's dressing was applied. Removal was suggested, and the patient was allowed to walk about as usual. After his admission into the hospital a week later, my attention was called to him by my house-surgeon, who told me that there was an interesting tumour which he wished me to examine. I found an oval tumour of the size of a large orange, or of a shaddock, situated in the hollow above the inner condyle of the femur, distinctly circumscribed and solid. On grasping it with my hand, pulsation was felt. The pulsation was not a mere impulse, or pushing inwards of the tumour *en masse*, but of the generally expansile character of an ordinary aneurism, communicated to the hand in every direction. There was a loud, harsh, rasping bruit. On compression of the femoral artery both bruit and pulsation ceased. Pulsation could not be detected in the popliteal artery in the normal situation of the vessel in the ham, but it was felt in both the tibial arteries, and the limb below the aneurism was of natural warmth and aspect. The patient was anaesthetised with chloroform, and Esmarch's bandage and strap were applied for an hour. Before removal of the strap the femoral artery was compressed, and on gradually allowing the admission of blood into the limb by the main channel, a slight pulsation and bruit could still be detected. A third of a grain of morphia was administered hypodermically, and digital compression was kept up for three hours, at the end of which time no pulsation could be felt. The patient complained of a burning pain in the foot, which was warmer than the right foot. The leg and thigh had been enveloped in cotton-wool and a flannel bandage immediately after Esmarch's bandage had been removed, and this casing was kept on till the following day. On the morrow, the 22nd of August, he still complained of a burning pain in his foot; there was neither pulsation in the tumour nor swelling of the limb. On the 25th it was noted that the pain in the foot had passed off, and that the tumour had diminished in size. On the 12th of September the tumour was less than half the original size, hard, not painful, with good pulsation in the tibial arteries. On October 3rd the patient was discharged cured. I must add a word of praise for the care and attention given to the case by my house-surgeon, Mr. J. G. Clark, and the dressers.

These cases raise several points of importance relating to Esmarch's bandage as a means of treating aneurism of the limbs, and to the diagnosis of aneurismal tumours. The value of Esmarch's bandage in the treatment of aneurism of the lower limb has been clearly established by several successful cases published in the journals or brought before the Societies. It is well known, however, that it is not uniformly successful by itself, and not always when aided by instrumental and digital compression. Sometimes it might prove injurious. It is quite possible that with the greatest care it might induce sloughing of the tissues over the sac, and it might also have the effect of causing gangrene of the limb through an excess of coagulation. It is scarcely possible to state beforehand whether a case is likely to be benefited by the treatment. One or two cases have come under my observation in which, after prolonged application of Esmarch's bandage, the symptoms were barely relieved, but after the lapse of a certain time from the application the aneurism ceased, as it were, spontaneously to pulsate. My impression is that the most favourable cases for the use of Esmarch's bandage are aneurisms of moderate size, firm and not too near the skin. My first case was decidedly an unfavourable case for Esmarch's bandage, and the bandage was only applied at the first trial for the purpose, if possible, of avoiding amputation, or the less hopeful procedure of laying open a large sac and tying both ends of the anterior tibial artery; and at the second trial, with a view to arrest hæmorrhage, place the patient out of immediate danger, and give him a chance of saving a limb which he seemed to prize more dearly than his life. Ligature of the femoral was of course out of the question under any circumstances, as it must have induced gangrene. Amputation had most in its favour, and amputation I should have performed the moment that I found that coagulation of the blood in the sac was incompatible with the life of the limb below. The extension of the clot in the sac into the anterior tibial above the sac, and even the lower part of the popliteal, is certainly suggestive of the possibility of gangrene arising in other cases

from a like cause; and I know not how the occurrence can with certainty be prevented. *Primâ facie* it would seem that the pressure of Esmarch's bandage might squeeze the blood from the sac into the feeding artery and even above it, and that this blood, remaining when the strap is applied, might coagulate, plug the vessels, and not be washed into the sac again when the current of blood through the main channels is restored. But I cannot speak with any certainty as to the extent of the liability to gangrene from such an accidental occurrence.

Of the two methods of applying Esmarch's bandage to an aneurism—viz., fixing the strap and removing the bandage, and pinning on the bandage without the strap, I think the former is preferable, as we can then make observations on the tumour such as might determine a doubtful diagnosis. But even here a caution is necessary. Free manipulation of an aneurism after the application of Esmarch's bandage might give rise to the very occurrence which we wish to avoid—viz., pressing blood or coagulum into the neighbouring vessels; and I am not altogether free from a remote suspicion that something of the kind happened in my first case at the second application of Esmarch's bandage, when a most excellent and careful surgeon made a minute manual examination of the tumour. It may or may not have been so. The liability to such an issue did not strike me at the moment, but it has arisen in my mind in the course of a retrospect of the case. At all events it may be wise to bear the possibility in mind.

The only other remarks which I have to make concerning Esmarch's bandage are: (1) that even when it is passed as lightly as possible over the sac some of the blood appears to be squeezed out of the sac, at least in my own cases in which this was done the sac seemed considerably smaller than before; and (2) that it might be advantageous, where the bandage aided by digital compression had failed, to inject a little perchloride of iron into the sac in combination with another application of the bandage. This treatment, however, I would only suggest for exceptional cases. In my first case, in which there was a ready-made aperture, I should have resorted to injection of the perchloride in combination with Esmarch's bandage, if the bandage alone had not sufficed to coagulate the blood.

(To be concluded.)

ON THE PHYSICAL DEVELOPMENT OF CHILDREN;

OR, THE BEARING OF ANTHROPOMETRY TO HYGIENE.

By PERCY BOULTON, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE SAMARITAN HOSPITAL FOR WOMEN AND CHILDREN.

BOTH in England and abroad much attention has of late been devoted to the study of anthropometry, and in its medical aspect I have for many years worked at the subject. I believe that it is likely to become a most valuable aid in preventive medicine, and merits the attention of everyone interested in the healthy growth and development of children.

A profession as far-reaching as the medical embraces everything that has to do with man materially in health and disease. It is chiefly owing to improved medical and surgical skill, together with sanitary science, that in recent years the value of life has been so considerably enhanced, and by prevention of disease we are further able to do much towards raising man to the full perfection of his physical being, so that the whole race should become by degrees man for man nearer the ascertained healthy type. From the physical point of view it is during the period of growth that mischief is done or can be averted, and hence the value of a reliable standard of height for weight during that period of childhood which lies between three and five feet. During this stage the arrested growth, if discovered, can generally be remedied, and if weighing and measuring were more systematically practised it would rarely escape notice.

When I commenced weighing and measuring ten years ago correct averages were unknown to me, and I had no idea how much a child should grow in a year, so that the scales and measure were practically useless. This child

seemed healthy and fat, that one thin, and the other a fair average, and the same as to height. I searched for some guide, and came across the work of Professor H. P. Bowditch of Harvard University, Quetelet of Belgium, and others in England, which was a sufficient guarantee that the subject was of importance.

Quetelet's conclusions summarised came to this:—1. That there is a perfect form or type of man, and that the tendency of the race is to attain that type. 2. That the order of growth should be *regular* towards the type. 3. The variations from the type follow a definite law, the law of accidental causes. These conclusions commended themselves to me, but Quetelet, Bowditch, Galton, and Roberts all treat the subject from the anthropological point of view, treating man as he is in the mass. Their statistics must be so mixed up with disease and all other accidental causes of variation, that their tables cannot be looked on as standards of health. Their method is to weigh and measure *once* large numbers of children as found together at public schools or in factories, and to classify them in columns according to *age*, and then to strike the mean of the whole number. Thus, boys between ten and eleven years were found to measure from 42 to 59 inches (a difference of 17 inches between the shortest and tallest). As 1943 children examined were arranged in columns, and the greater number fell into column 50 to 51 inches in height, this is taken to be the standard or average for boys from ten to eleven years. This, I think, shows the fallacy of an age standard, for while 331 fell into this column, 1612 were "out of it" altogether, 816 being below and 796 above the mean.

The work of Roberts is very elaborate and complete. Having examined 50,000 factory and other children, these tables are no doubt correct standards of the physical averages of such children, and form a more reliable guide as to their capacity for work than certificate of age, which is the most unreliable of standards. The Acts of Parliament require that every child shall have the strength and appearance of at least eight years of age, and a *young person* at least that of thirteen years, for employment in their several capacities. The necessity, therefore, of a standard of physical averages at these ages is evident. Roberts's tables are intentionally fixed at the lowest point of physical fitness for work, which renders them unreliable as a typical standard for healthy English children brought up under favourable circumstances. A glance at the difference of physique between the children of the poor in a manufacturing district and of those that can afford to feed and care for their children well, is sufficient to convince that our standard must be higher than any average taken from such a source. As a fact, I have found my averages come out higher in both height and weight. In Belgium, America, and England, up to twelve years of age boys and girls average about the same height and weight. In America, Professor Bowditch says that girls are taller and heavier than boys. In Belgium they are the same at twelve years, and in England I find that, for all practical purposes, they may be taken together up to 5 feet. After 5 feet there is an appreciable difference, as girls arrive at puberty and cease growing sooner than boys.

Seeing that an age standard is perfectly unreliable, and that healthy children vary so much in height, it appeared likely to me that there are varieties of types depending on different rate of growth; so the first two points that I set myself to decide were—1. The rate of growth per annum of average healthy children. 2. Their weight for height. Instead, therefore, of making 200,000 *single* observations, as done by Bowditch and Baxter in America, I have examined the same children at least once annually, and kept careful records of the results over a space of ten years. In order to get a typical standard of weight for height the children were selected as average children of healthy well-to-do parents, brought up with suitable food and surroundings, giants and dwarfs being excluded. By this means I have been able personally to watch and record their rate of development under identical circumstances, and to glean interesting and reliable information on some points.

The table which I have drawn up may be looked upon as a typical standard for weight and height, and as it should be our aim to see every unit of the population brought up to the maximum of healthy development, I believe it will be found a reliable guide, subject to other statements which I shall shortly make. Observations of weight without height are of no scientific value, so that in this, at any rate, our clever artist, Mr. Marks, is right in the assertion that "science is measurement."

The masses of figures that have had to be digested in drawing up my table would be dry and difficult to follow, so I shall only give results.

Annual rate of growth.—The fact that different healthy children grow at different rates explains the circumstance of varying height in healthy individuals. I find that average English children brought up under favourable circumstances grow from 2 to 3 inches a year. A growth of less than 2 inches or over 3 should excite apprehension. The former would indicate arrested development, and the latter a rate of growth beyond the powers of average children. Rate of growth should be regular, and being so, prognosticates future stature, because the healthy child that grows 2 inches a year passes 5 ft. at about fifteen, which indicates a short stature (i.e., if a male, about 5 ft. 6 in.; female, about 5 ft. 1 in.). The healthy child growing $2\frac{1}{2}$ in. a year is 3 ft. 2 in. at three years, and passes 5 ft. at thirteen to fourteen years. Such child will be a medium-sized adult (i.e., if a male, about 5 ft. 8 in.; female, about 5 ft. 3 in.). The quick-growing healthy child that accomplishes 3 in. a year passes 5 ft. at ten or eleven, and eventually makes a tall adult (i.e., if a male, about 5 ft. 10 in.; female, about 5 ft. 5 in.). So rate of growth might be likened to three trains travelling at, say ten, twenty, and thirty miles an hour; the fastest train, of course, covers the most ground in a given time, subject somewhat to the exact point where puberty puts on the brake, which at first slows, and ultimately stops the progress altogether. Of course, one meets with many variations, but these variations are, I believe, always abnormal. Some children seem to do their growing by fits and starts, the common diseases of children arresting for the time their progress, which is made up for afterwards by a supreme effort. Such growth is unnatural and often very detrimental. I believe, then, that every healthy child has its own regular rate of growth of 2, $2\frac{1}{2}$, or 3 in. a year, from which it has no right to vary more than $\frac{1}{4}$ in. a year.

Next as to weight for height. Whether a child grows 2, $2\frac{1}{2}$, or 3 inches a year, weight for height should be in each case identically the same, and all healthy children should grow broad in proportion to their height. Between 3 and 4 feet the increase in weight should, I find, be 2 lb. per inch, and between 4 and 5 feet $2\frac{1}{2}$ lb. per inch.

I do not wish it to be thought that the table which I offer as a standard is a precise statement of what has come out of my statistics. I wish it to be understood that statistics do not accommodate themselves to the regularity of half-pounds, as found in this table. An observant and accurate statistician may, however, very easily lay down a law from the facts and figures which he has to deal with. It is a fact that my statistics came out 2 st. 8 lb. for 3 feet, and 4 st. 4 lb. for 4 feet, and 6 st. 6 lb. for 5 feet, and having found 2 lb. per inch to be the normal increase between 3 and 4 feet, and $2\frac{1}{2}$ lb. per inch between 4 and 5 feet, the rest naturally follows, and has proved a reliable approximate working standard.

Feet	In.	st.	lb.
3	0	2	8
3	1	2	10
3	2	2	12
3	3	3	0
3	4	3	2
3	5	3	4
3	6	3	6
3	7	3	8
3	8	3	10
3	9	3	12
3	10	4	0
3	11	4	2
4	0	4	4
4	1	4	$6\frac{1}{2}$
4	2	4	9
4	3	4	$11\frac{1}{2}$
4	4	5	0
4	5	5	$2\frac{1}{2}$
4	6	5	5
4	7	5	$7\frac{1}{2}$
4	8	5	10
4	9	5	$12\frac{1}{2}$
4	10	6	1
4	11	6	$3\frac{1}{2}$
5	0	6	6

Some children exceed these weights that are by no means giants; and really healthy, well-nourished children of healthy

parents and favourable surroundings generally attain these averages. But what of children that fall below the standard? I find that there is a 7 lb. margin of safety, and that children falling more than 7 lb. below this standard are devoid of reserve capital on which to draw, and consequently they succumb quickly to many constitutional diseases. This, therefore, may be called the preventive medicine margin, beyond which lies the dangerous land of cachexia.

Arrest of growth, or loss of weight, precedes so many diseases that it may be looked upon as a danger signal, and if the "caution" is noticed before the disease point is reached catastrophe may frequently be prevented, and so childhood may be worked on a kind of "block system." It is thus that it becomes of such value in preventive medicine.

In pulmonary consumption loss of weight generally precedes cough, and, according to Dr. Dobell's table No. 4, hæmoptysis only occurred 8 times out of 100 cases before loss of weight had been noticed. Moreover, while cough is a symptom at once recognised and noticed, loss of weight is so insidious that it is apt to go some time unnoticed. The number of cases in which loss of weight began before cough is sure to be understated. These remarks apply more strongly to the cases in which loss of weight preceded first hæmoptysis—a symptom never overlooked.

I have been glad to notice that lately there have been evidences in various quarters that this subject is attracting attention. At the International Congress at Amsterdam Professor Donders in his most eloquent address said, that "the principal aim of hygiene is contained in the factors—the desire to raise man to the full perfection of his physical and moral being, the principles of gymnastics, that are yet but little known, the doctrine of heredity, the influence of consanguinity," &c. Dr. Zeeman, of Amsterdam, in speaking of the best methods for measuring public health, dwelt on "the physical development of infants and youths, and the results which have partly been obtained, or will be obtained in the future, by a series of careful investigations, which are classified under the name of anthropometry." At the meeting of the British Medical Association at Cork Dr. Rabagliati touched on the same subject.

As a practical example of what has been done through the knowledge of a physical standard, let me instance what occurred at the Boys' Home, Regent's-park. In 1875 it was found at that institution that the boys had not increased on an average two inches a year, so in January, 1876, a revised dietary was used, and it was found, after one year, that by this simple change the average increase amongst the boys had been over two inches in stature, and 6½ lb. in weight.

It is not possible in this paper to go into the question *how* the standard is likely to be more generally attained; but, speaking broadly, the principles of sanitary science, food, clothing, work, rest, pure air—in short, the proper bringing up of children is the foundation. It is merely stating a truism to say that suitable food and surroundings are necessary for the healthy development of every living thing; and that overwork of the young, whether mental or bodily, ill-feeding, sickness, hereditary diseases, and the like, cause children to be puny and fall below their proper averages. Diseased and diminutive parents are apt to procreate undersized and unhealthy offspring, which nothing will make grow up to a typical standard, for the embryo receives a stamp at the time of conception which would baffle all our subsequent efforts for its welfare. But children born of healthy parents are constantly being added to the roll of the weedy and undersized owing to want of care during the growing years. For all such the scales and measure offer indications of no mean value. Much might be done by sanitary, medical, and general inspection of children's homes, and by establishing child-colonies, as in Switzerland, America, and Saxony.

Our school boards might become a great power for the physical improvement of our rising population, if some of the monstrous sum expended in teaching our labourers and servants of the future the rudiments of science, mathematics, and German were utilised during school vacation in sending the undersized to the country under the care of their teachers, and opportunity were afforded them to become physically strengthened by judiciously regulated diet, plenty of exercise in the fresh air, &c.; if, in short, a little less were done for the *mens sana* and a little more for the *corpore sano*. It is perfectly wonderful what only three weeks of change to the country has been found to do for town children thus treated in Saxony. In Switzerland and America the children are placed in the families of farmers, who take charge of

them for a small sum—a system of "farming out" not as yet known, I am sorry to say, in this country.

The medical inspection of schools which has been instituted in the department of the Seine is a step in this direction which might be imitated in this country with advantage, and I would strongly urge the triennial use of the scales and measure as the most trustworthy indicators of the physical welfare of the rising population. There is little doubt that the mental pressure which is now so common in elementary schools causes an excessive waste of nerve force for mental work, which should be subservient to bodily growth and development. Mental overstrain is most common amongst the poor who suffer from want of food and bad hygienic surroundings, but it is not uncommon amongst the growing children of the rich; and it is important that parents should be aware of the possibility of sacrificing physical to mental development. The reverse may certainly occur, the result being a fine but not very intellectual animal; and therefore in this, as in most things, it is the "happy medium" that is the best and safest.

Seymour-street, W.

CASE OF CEREBRO-SPINAL MENINGITIS; DEATH AND AUTOPSY.

By TOM ROBINSON, L.R.C.P. LOND., &c.

A. G—, aged eight, was a cheerful and intelligent schoolboy. Father and mother both living and healthy; have four other children all living and well. On July 21st whilst at school the mistress noticed that he was dull and sleepy, but he got through his lessons in the morning and came home crying with pains in his head. His mother gave him castor oil, after which he vomited.

On July 22nd he was quite delirious, complaining of intense pain in his head. On the evening of this day I saw the boy and found him lying in bed and on his back. He was rolling his head about and complaining of great pain. I did not distinguish any irregularity of pupils or paralysis of muscles of eyeball or elsewhere. He was extremely irritable. No evidence of any disease or eruption. Temperature 102° 2'; pulse 126; respiration 32.

July 23rd.—His right eye attracted my attention on going to his bedside. The pupil was very dilated, insensible to light, and the cornea looked steamy. He was still lying on his back, moaning and complaining of pain in his head, particularly when moved about. He said he could see a candle, but he could not count my fingers or tell those around him. Temperature 102° 2'; pulse 103; respiration 31.

24th.—Mr. Hutchinson saw the case with me. On his first visit the patient was lying on his back with the knees drawn up, almost touching the chin, very delirious, and screamed violently on being disturbed. The steaminess of the right eye had become opacity, and from the evidence we concluded he was blind on this side. There was marked increased tension of the globe. Temperature 103°; pulse 124; respiration 30.

25th.—Head thrown back and very fixed. His gums were inflamed from repeated doses of calomel. His eye was much the same. Temperature 102° 2'; pulse 123; respiration 30.

27th.—Quite conscious. Slept well during the night. His left eye was normal, but with the right he was totally blind, and the iris was invisible. Temperature 100°; pulse 120; respiration 30.

31st.—His condition had not much changed. He had slept for long periods both night and day. Complained of great pain when he was moved. Could lie on either side, but his head was always drawn back, and he resisted any effort to flex it. Temperature 99°; pulse 120; respiration 30.

Feb. 2nd.—I made the following notes: "On the right eye there is marked bulging on the upper aspect, which bulging is brown. I can now see through the cornea, and discern the iris distinctly, but there is an opaque patch on the cornea which obscures the pupil. He is conscious, does not like to be disturbed, and says his legs pain him. Temperature 100°; pulse 120; respiration 24."

10th.—Wasting very rapidly, but more cheerful. The bulging on the globe is less; the cornea is more transparent;

the pupil is triangular. The vision of the left eye remains good. Temperature 96.2°; pulse 110; respiration 20.

14th. — Dr. Wilks saw the case in consultation with me. On our visit the boy was cheerful, was lying on his left side, and had no pain or difficulty in turning from side to side, but moved his head and shoulders as if fixed. He complained of pain in his neck. When he sat up his head seemed too heavy for his body, and he begged of us to put him on his pillow. With the exception of the right eye, there were no other discoverable physical signs. Temperature 97.8°; pulse 108; respiration 20.

21st. — Quite conscious. Often complains of cold, and when he does so his cheeks look like gooseflesh. When asked to sit up he says he cannot. If an attempt is made to lift him he cries, but his head may be rotated and extended without any resistance. Vomits after food. Complains of the slightest noise. Temperature 98°; pulse 107; respiration 21.

March 2nd. — Has not slept all night, and was wandering incessantly, lying on his right side, with his legs drawn up. The right eyeball is getting smaller, but is quite sightless. Temperature 102.8°; pulse 110; respiration 22.

12th. — Since the last note he has been very irritable and restless. Has complained much of pain in his head, and asks to be left alone. He vomited at frequent intervals. Is delirious at times. Picks his face, and chatters a great deal incoherently. Temperature 98.4°; pulse 100; respiration 20.

19th. — Seems very much better. Answers questions rationally. His hearing and sight of left eye seem quite normal. He takes his food, and does not vomit. Still looks extremely ill. Temperature 99°; pulse 98; respiration 22.

26th. — Since the last note his right eye has given way in the upper aspect, and is discharging pus. Complains bitterly of his head, particularly when moved. Temperature 99°; pulse 110; respiration 24.

April 10th. — He has not exhibited any material alteration since the last note was made. He looks very careworn and old. Has incontinence of urine and faeces, and is terribly thin. There are some aphthous patches in his mouth. He will answer questions, but the response is slow and monosyllabic. Temperature 98°; pulse 124; respiration 22.

16th. — There is a band of herpes over the sixth right dorsal nerve. There are on his abdomen a number of purple spots, which do not disappear on pressure. The saliva dribbles from his mouth, and over his body in such positions as the helix the skin is dead, but only the skin. When he is raised his head falls back, and he cannot move it without assistance, at least he does not. Temperature 99.2°; pulse 126; respiration 24.

21st. — He goes scarlet in his face at times. Is absolutely unconscious to reflex action or questioning. Breathing in short rapid gasps, which are irregular. Sweats on the least exertion. Swallows with great difficulty. He died during the night. Temperature 99.8°; pulse 144; respiration 68.

Autopsy, twenty-four hours after death. — The body was very much wasted, and the muscles about the neck appeared more so than any other part of the body, the transverse processes of the vertebrae standing out in relief as the body lay on the table. The abdominal and thoracic viscera were healthy. Head: The pia mater on the surface of the brain was shining and normal, but as you looked towards the base of the brain this membrane became greasy, which greasiness gradually became opacity, and on the under surface, matting together the optic commissure and other structures, was an opaque covering, which was firm. This opacity was continued on each side into the Sylvian fissures. The convolutions of the brain were flattened. The lateral ventricles were much distended by about six ounces of thick fluid. There was no evidence of tubercle or injury to the skull. I was forbidden any examination of the spinal cord.

The points of interest in this case are three.

1. The destructive process which so suddenly attacked the eyeball.
2. The cutaneous conditions which arose during the boy's illness.
3. The want of evidence as to the cause of the meningitis.

The first two, I think, must be attributed to alteration in nerve-function. I have seen cases where, after affections of the brachial plexus, either from injury or other causes, the fingers have become withered and glazed, and one need scarcely say how much modern pathology has done to demon-

strate the connexion between nerve changes and several forms of skin disease. In the museum of St. Bartholomew's (Series 9, No. 9) is a case of penetrating ulcer of the cornea, which occurred in a case of tumour near the pons, which tumour destroyed the trunk of the trigeminal. And Sir James Paget writes in his work on Surgical Pathology, "It is well-known that when the trigeminal nerve is divided the eyeball inflames, so that within a few days its textures may be greatly injured, or even destroyed, by the inflammation."

I have under my care at the present time a young lady whose fingers and toes are an indigo blue, which blueness disappears on pressure, is not changed by position, but passes away when she has been near the fire for some time. Her fingers are very painful and she cannot feel the pricking of a pin. This patient has cherry-coloured lips and is free from organic disease of heart; so we must believe she has, from cold, a paralysis of those nerves which govern the arterio-capillary venous network, which vessels are simply, as Dr. W. H. Stone has shown, closed cells. So that I think I am justified in stating that the destructive inflammation which took place in my patient's eyeball was due to the destruction, or partial destruction, of the trigeminal nerve by the inflammatory process which took place at the base of his brain; and I apprehend his herpes zoster and his cutaneous gangrene were attributable to the same action, involving other nerves.

In the absence of any history of an injury, or growth, or fracture of skull, one is compelled to accept this as a case of idiopathic cerebro-spinal meningitis, such as is described by Niemeyer under the term epidemic, and by many other writers, and it is found that isolated cases have been reported from time to time. Thus Dr. B. W. Richardson saw an unquestionable case at Mortlake in 1843 (*Social Science Review*, May, 1865, p. 398). Dr. Wilks has reported cases which he has met with during each of the three years 1856, 1858, and 1859, in London, and I remember a case occurring in the London Hospital during the year 1870. The difficulty arises as to whether the case I have ventured to make public is a true example. It certainly presented all the objective symptoms, and the pathological evidence would demonstrate that it was a cerebro-spinal meningitis.

Guilford-street, Russell-square.

FIVE YEARS' SURGICAL WORK IN THE CARDIFF INFIRMARY.

BY ALFRED SHEEN, M.D.,
SURGEON TO THE INFIRMARY.

(Continued from p. 533.)

Dislocations. — Under this heading there are but few entries, chiefly because dislocations as a rule are dealt with as out-patients. The elbow case had a stiff bandage applied in ten days, and was made an out-patient. It was a dislocation backwards, complicated by fracture. The shoulder cases were both of some standing—one being thirty days, and the other nine months. The first was in a man aged fifty-four, and was reported in THE LANCET at the time.¹ On admission, there was flattening of the left shoulder, prominence of the acromion, lessened mobility of the arm, which was somewhat from the side, and pain on trying to raise it. No swelling or crepitus; slight prominence in front of the joint; head of the bone to be felt in the axilla. The patient was placed fully under the influence of chloroform, the limb was manipulated to break down any adhesions which had formed, and reduction attempted, but without success. A further examination of the limb was then made, and on rotating the arm with my fingers placed on the head of the bone the latter was found not to move. The diagnosis was: original accident, fracture of the neck with dislocation, and now disturbance of fractured ends. In Guy's Hospital Reports for 1875, p. 132, I find a somewhat similar case thus recorded:—"Mr. Howse attempted to reduce an unredacted subcoracoid dislocation of the right humerus of one month's standing. With the patient under chloroform, Mr. Howse attempted to violently break down the adhesions, and in doing so fractured the humerus, pro-

bably at the surgical neck. Attempts were afterwards made to reduce it with the heel in the axilla, but without success. The lower fragment slipped up somewhat in the normal position of the humerus, whilst the head remained fixed in its subcoracoid position." Mr. Jonathan Hutchinson subsequently made some comments on my case,² with a view of showing that it was most probably one of fracture of the neck without dislocation. I have seen cases of fracture of the neck since, and I am still inclined to believe that the case I have here commented on was a fracture *plus* dislocation, although this may be a rare accident, and such was the opinion of my colleagues who saw the case in consultation. The chief point upon which I relied was the fact that the head of the bone was felt in the axilla after the fracture had occurred. The second case was in a woman, aged sixty. On making an attempt at reduction under chloroform, I broke the bone at the neck, it giving way with a loud snap. The arm was brought to the side, which could not be done before, and the patient was subsequently discharged with a fair amount of motion, and satisfied with her condition. There was no snap of any kind in the first case, and this helped to confirm me in my diagnosis of that case.

DISLOCATIONS.

	Under ten. M.	Under twenty. M.	Under forty. M. F.	Under sixty. M.	Over sixty. F.	Totals. M. F.
Shoulder ..	0	0	0	0	1	1 1

Hip	1	1	1	0	0	3 0
Ankle	0	0	1	0	0	1 0
	1	1	3	2	1	7 2

Both clavicle cases were dislocations of the acromial end, which Mr. Bryant, following Skey, MacLise, and Flower, says should be called dislocation of the *scapula*. They were both caused by direct violence, and were admitted within a fortnight of each other. One case was put up in a stiff bandage, and the other in broad strapping under the elbow and over the shoulder. The dislocated hip in a child was of eight months' duration, and was interesting in more ways than one. At the time of the accident the child was taken to a chemist, who, of course, failed to recognise the nature of the injury, but had the audacity to treat it as something which it was not, and for a month previous to admission it was treated by a medical man, who presumably ought to have known better, as a case of hip disease, and was sent into the infirmary for the purpose of having a stiff bandage applied. No attempt at reduction was made, as a false joint had formed, and the child had good use of the limb. The second case of hip disease was of eight weeks' standing, and an attempt at reduction under chloroform failed.

Of simple fractures there are 105, 90 being males and 15 females. The proportion of females is unusually small, and this is due in some measure to the absence of those industries where women would be employed. I think there is only one such establishment in this neighbourhood—a paper mill; but although many accidents occur here they are all amongst men, and this is probably due to the fact of the women being kept out of the way of the machinery.

Two of the cases of fractured skull died within twenty-four hours of admission, one being admitted in a moribund state. All the cases of fractured spine died, three within

twenty-four hours of admission. The case of fractured pelvis was interesting. It was in a painter, aged forty-eight, who fell thirty feet whilst painting on the second landing of a staircase, coming down on his buttocks. When admitted he had intense pain in the pelvis, much bruising in the sacral and coccygeal regions, partial loss of power over the lower extremities, and contusion in the right iliac region, with crepitus on pressing both sides of the pelvis. His easiest position was a prone one. When a catheter was passed, a few hours after admission, half an ounce of dark-coloured urine was drawn off. After a further interval of some hours half an ounce of clear urine was drawn away. Next day he passed half a pint of clear urine. Eleven days afterwards there was a bed sore over the sacrum, although he had been on a water-bed since admission, and redness and swelling over the left iliac region, extending upwards, and his temperature went up to 101° F. An abscess formed in the loin, and in nine days broke, giving exit to about one pint of pus, followed by a quantity of clear urine, and his temperature became normal. In twenty-four hours two pints and a half of clear urine escaped from the opening through a drainage-tube, and none came per urethram. He died exhausted three days after. I suppose that in this case the left ureter had been ruptured, but unfortunately the body was allowed to be taken away by the friends without a post-mortem.

As to treatment in cases of fractured thigh, Lister's long splint was almost invariably used at the commencement, and a stiff bandage applied as soon as possible, varying from six to twenty days after the receipt of injury, with cure, and in most cases little or no appreciable shortening. One case of fracture of both thighs in a child aged four and a half years was treated by slinging his limbs, as recommended by Hamilton in his work on "Fractures and Dislocations," and afterwards by stiff bandages. He was running about the ward five weeks and a half after the accident, but the limbs were not quite straight. The case of fracture of both legs and one thigh was sustained in a railway collision, and did well, the patient being discharged fifty-five days after the accident. The cases of fractured patella were treated by simple elevation of the limb, to take off all strain of the muscles, and as soon as all swelling had disappeared a stiff bandage was applied. The results were admirable. Fractures of the leg were mostly treated by Cline's splints, and the early application of a stiff bandage. The average stay in hospital of such cases, where there were no complications, was fifteen days. I am a strong advocate for the early application of a stiff bandage in simple fractures of the limbs. They may be put on with advantage immediately after the accident, if there be little or no swelling; in other cases, so soon as the swelling has subsided. This treatment enables the patient to take early exercise, which is beneficial to himself, and the surgeon to make an out-patient of him at an early date, which is a great gain to the funds of the institution. Up to quite recently we have used a mixture of *gum and chalk*, which forms a capital support of the requisite strength, but since the introduction of muslin bandages we have used *plaster-of-Paris* applied over a stocking. These bandages are preferable, because the limb can be held in position whilst the plaster sets.

Of compound fractures I have had the large number of sixty-six cases, and more than one-third of these were what I may call "railway smashes." The Great Western line runs through the town, and in addition we have the termini of the Taff Vale and Rhymney railways, and from the former of these two most of our serious accidents are supplied. Although an admirably managed line it is a dangerous one to the workmen employed, and this familiarity with danger makes them somewhat careless. More than half the cases were of such a serious nature as to require immediate amputation, and remarks upon these cases are given under the heading of "Amputations for Accident." One or two cases I may draw attention to.

No. 26.—G. T. S.—, aged fourteen, fracture of femur. Carbolic-acid lotion, one to twenty, was injected into the wound, which was, after the lotion had drained out, sealed with styptic colloid, and Lister's long splint applied. Cline's splints were applied to the fractured leg. The patient did well, and two months after his discharge the report upon him was, "Can walk as well as before the accident; no shortening."

No. 64.—P. M.—, aged fourteen. Compound fracture of humerus and radius, put up antiseptically; five dressings; bony union and fair position in twenty-three days.

² THE LANCET, vol. i. 1876, p. 341.

No. 46.—J. Y—, aged thirty-two. Compound fracture of leg. Put up antiseptically; five dressings. Stiff bandage in twenty-four days. Temperature chart, a straight normal line throughout.

No. 41.—W. E—, aged fifty-three. Compound fracture of leg. Wound sealed with styptic, and a stiff bandage applied in fourteen days.

As to cause: Nos. 12, 16, 17, 18, 21, 23, 24, 25 to 34 inclusive, 36, 37, 38, 42, 44, 51 to 59 inclusive, and 63, were railway accidents; 14 was from a gun explosion; 39 from a reaping machine; the remainder occurred in various ways.

There were sixteen deaths. Of these two were admitted moribund; one, a smashed chest (No. 23), died in six hours. In No. 25, a severe compound fracture of the thigh, an attempt was made to save the limb by antiseptic treatment, but the injuries to the soft parts were so great that gangrene supervened, and the patient succumbed on the third day. In No. 21 there was, no doubt, injury to the brain. No. 50,

a compound fracture of the leg, died in twenty days from pyæmia. No. 39 is a fair illustration of the dire results which sometimes happen from the prevailing ignorance of the immediate and temporary treatment of injuries, an ignorance which the St. John's Ambulance Association is making most praiseworthy efforts to get rid of. The patient, a boy, aged eleven, got his foot cut off by a reaping machine. His leg was tied up in some fashion. He was driven in a cart to the infirmary, a distance of six miles. There was much bleeding on the way, and the poor boy died half an hour after admission. Of course, we have much more serious accidents in railway smashes, but in these, the wounds being lacerated, the vessels are mostly twisted, and serious hæmorrhage, as a rule, prevented. Case No. 53 was that of a gentleman who was deaf and dumb, who strayed on to the railway, and was knocked down by an advancing train from behind, whose approach he was unable to hear. He was dreadfully injured, and died just as a lower limb had been separated from the trunk, and the stump trimmed.

The treatment of these cases of compound fracture has been of various kinds. Where there is not much damage to soft parts, and the bones are easily kept in apposition, *styptic colloid* is always a favourite application with me, with a view to closing the wound, and in some cases it has answered admirably. The "antiseptic treatment" has been fully carried out in some cases, imperfectly in others. It is one of the disadvantages of this treatment that unless you give *personal* attention to all its details you cannot ensure that amount of success which, I think, fairly belongs to it. So far as I have practised it I should give it the palm over every other kind of treatment, as tending to remove all fear and anxiety as to constitutional disturbance and bad symptoms. I should not be guided much by statistics with reference to the antiseptic treatment. We all know what tedious cases compound fractures were, as a rule, previous to the introduction of "Listerism," and many of us know now how differently these cases progress, and are able to appreciate at their proper value the lessons which Professor Lister has taught us. Whether his *method of practice* is the best which can be devised probably remains to be decided hereafter.

PREMATURE LABOUR INDUCED BY QUININE.

By E. DOWNES, L.R.C.P. LOND.

It is sometimes questioned whether quinine does or does not induce labour when given to pregnant women. It is not often necessary to give it in England; but in India, where ague is so common, it often becomes a serious question whether to give it or withhold it in pregnancy. A case has just occurred to me which bears out the idea that quinine does induce labour.

A lady placed herself in my hands; she expected her confinement at the latter part of August. In the middle of July she had bad fever, which, originally of an intermittent kind, showed a tendency to become continuous. I endeavoured, with some success at first, to keep off the fever by jaborandi and arseniate of quinine, without giving the sulphate of quinine. The amount of quinine in the arseniate was so small that I did not fear giving it. Nearly a month passed and the fever was so bad and intractable, and she became so weak, that I began to fear the consequences both to mother and child; so, on the 7th of August, I resolved to give quinine. I gave it in five-grain doses, which I ordered three times a day. She took two doses—one in the morning and the second at mid-day. At about 8 o'clock in the evening, without any warning, the "waters burst," and slight uterine pains came on. They were, however, very slight—so much so that she doubted whether she was in labour at all, until at about 11 o'clock the pains became a little stronger; one or two sharp pains succeeded, and the child's head, followed after a few moments by the body, was born. The placenta came away about half an hour afterwards without hæmorrhage. The child was very small, and looked as though it had been born a month before its time. A great deal of its skin peeled off, and after a week it became very much jaundiced, but it promises to do well.

There can be little doubt that the moderate doses of quinine which I gave caused the birth of the child, and under the circumstances it was perhaps the best thing that could have happened. But I shall be careful that I do not give quinine to a pregnant woman again unless I feel that I am obliged to do so. In the case which I have recorded I deliberately chose the induction of labour as a less dangerous alternative than the continuance of the fever.

MIDDLESEX HOSPITAL.

CASE OF LYMPHADENOMA; OPERATION; RECOVERY.

(Under the care of Mr. GEORGE LAWSON.)

FOR the notes of the following case we are indebted to Mr. Duff.

Wm. C—, aged thirteen, a fair-haired, delicate-looking boy, was admitted into Pepys ward on April 20th, suffering from a large tumour of the lymphatic glands in the neck. The boy's father was subject to cough, but was otherwise healthy; his mother was also healthy. There were three sisters younger than the patient, all of whom were healthy. The boy had had whooping-cough, measles, and scarlet fever. About three years ago he first noticed that he had a small lump behind and below the right ear. The lump grew downwards until it reached a little below the clavicle. The mass then spread forwards and backwards. There had been no difficulty in swallowing, and no pain until about a fortnight before admission, when he first began to feel discomfort in the back part of the tumour. About twelve months ago he first noticed a swelling about the size of a marble in the left groin; this steadily increased in size.

On admission, there was on the right side of the neck a large tumour of a somewhat triangular shape, having its apex at the mastoid process of the temporal bone, and its base extended round the root of the neck. In front it passed slightly beyond the mesial line, and had pushed the larynx and trachea over to the left. Behind, it reached to within two inches of the spinous processes of the vertebrae. Below, the tumour overlapped the inner two-thirds of the clavicle, and extended down to the lower border of the second rib. The growth was crossed by the sterno-mastoid muscle, and was overlapped by the edge of the trapezius. The surface of the tumour was lobulated, and over the lower part the skin was reddened. It was apparently composed of a mass of enlarged glands matted together.

In the left groin there was a similar tumour, but very much smaller, about the size of a large horse-chestnut. The boy looked very pale and anæmic, his complexion being remarkably clear and semi-transparent, with a slight hectic

blush. He slept well and his appetite was good, but he complained that he soon tired when at play. Owing to the size of the tumour, his face was kept turned slightly to the left, and when he wanted to look to the right he had to

turn his body. Heart and lung sounds normal; blood examined by the hæmocytometer, 4,560,000 red corpuscles in cubic millimetre; 20,000 white corpuscles in cubic millimetre.

April 28th.—The patient was taken into the theatre and Mr. Lawson removed the tumour, which consisted of masses of enlarged glands matted together in groups. A transverse incision was first made on a level with the clavicle, and from its anterior extremity the knife was carried upwards in a line with the sterno-mastoid to behind the lobe of the ear. A flap of skin was then turned up, and after a little dissection and enucleation with the finger and handle of the scalpel, the whole of the tumour was turned out. The edges of the wound were united, and a drainage-tube was inserted into the posterior and most dependent part of the wound. The wound was then covered with a pad of lint soaked in terebine oil (one part in ten). Cotton-wool and carbolic gauze were then placed over the whole and kept *in situ* with a bandage. The right arm was bandaged across the chest. He did not sleep well, and vomited several times after the operation, probably from the effect of the anæsthetic. The wound was dressed next day with the terebine oil and covered with carbolic gauze. Temperature 99° 8'; pulse 120. As he continued to vomit everything he took all food was omitted for a time, and a little ice was given to suck. A nutrient enema was administered containing half an egg, half an ounce of arrowroot, two drops of tincture of opium, and one ounce of beef-tea every three or four hours.

On the 30th he was able to keep down a little beef-tea. The tongue was moist, pulse 120, temperature 100° 6'. The enemata were discontinued. From this date the boy progressed favourably, and the wound completely healed. When near convalescence the boy had an attack of erysipelas of the neck and face, which detained him in the hospital. At the end of June he was discharged, to go to Eastbourne.

Remarks by Mr. LAWSON.—This lad presented the characteristic appearance of the disease known as lymphadenoma, first described by the late Dr. Hodgkin (Med. Chir. Trans. 1832, vol. xvii., p. 68). In the anæmic condition of the boy, and in the excessive growth of the glands in the neck, the case corresponded to that so fully described by the late Dr. Murchison in the Path. Trans., vol. xxi., p. 372. The tumour was removed because it gave pain, and as it was rapidly increasing it was likely to interfere with breathing, for it had already pushed the trachea considerably to the left side. The history of similar cases made the ultimate prognosis unfavourable. The glands in the abdomen and chest are always prone to become similarly affected, and deposits, resembling lymphatic-gland tissue, to take place in the liver, spleen, or kidneys. The operation was the means of affording great relief to the local symptoms, and of improving, for a time at least, the general health of the boy.

ASHBURTON AND BUCKFASTLEIGH COTTAGE HOSPITAL.

PLASTIC OPERATION FOR CONTRACTING CICATRIX.

(Under the care of Dr. JAMES ADAMS.)

J. S—, aged fourteen, was admitted on Oct. 30th, 1879. This boy in November, 1876, was severely burned by the ignition of gunpowder in his pocket. He was admitted into the hospital four months afterwards in a state of extreme prostration, with a bad bed sore. He had diarrhœa, and frequently passed motions involuntarily in bed. The burn included the whole right side of the abdomen from two inches left of the mesial line to the lumbar region, the anterior and inner aspect of the right thigh, the skin over right patella, and a small patch about the size of half a crown two inches above left nipple. The condition of the burn was very unhealthy. After being an inmate of the hospital sixteen months, he was discharged with the burn cicatrised; but in spite of frequent skin grafting, and the application of a heavy weight to the affected side, the cicatrix had begun to contract before his discharge.

On his readmission there was a thick and hard cicatricial band at the bend of the hip joint, causing the boy to stoop considerably, and rendering him unable to extend his thigh beyond an angle of 140° when lying on his back.

On Oct. 31st, under chloroform, the contracting band was freely divided an inch below Poupart's ligament, and a weight of 3 lb. was fixed to the leg. On extension the

wound gaped three inches and a half. It was dressed with carbolic oil (1 to 30). A week later one or two small bands at the bottom of the wound that were tense, and prevented the limb lying comfortably straight, were divided.

On Nov. 8th a Lister's splint was put on the left side.

On the 22nd the wound was filled with healthy granulations, and measured four inches from the upper to the lower edge, and rather more in the transverse direction, and was lozenge-shaped. A piece of healthy skin with subcutaneous tissue was carefully dissected out at the outer side of the thigh over the trochanter, leaving a neck of skin at the point joining the wound, and a bed for the graft having then been made by removing the granulations to the depth of one-sixteenth of an inch, and of the required size (two inches by an inch), the flap was fixed in its place by five silver sutures. These were firmly and deeply embedded by means of a nævus needle. The graft took well; a small portion of the end of it sloughed, owing, I believe, to the suture there being rather tighter than it should have been.

On Dec. 8th the neck of the graft, which was firmly adherent in its new situation, was divided. At the same time the skin and subcutaneous tissue were divided about three inches above the knee, where there was some tension. The lips of the incision separated one-fourth of an inch. Once subsequently a similar incision was made, two inches higher up the thigh, followed by a similar gapping.

The transplanted skin covered only a very small portion of the large traumatic ulcer, which was healed up by the use of different stimulating lotions. At first the healing process was fairly rapid, but afterwards it was quite the reverse, and the last fourth took as long to heal as the first three-fourths.

The whole time, with but few intervals, a weight was kept fixed to the leg varying from 1 lb. to 7 lb., the medium weight of 3 lb. being chiefly used, and this he still has at night. The Liston's splint was also kept up the whole time.

The boy was discharged on July 17th, 1880, having gained at least 3 in. on his right side as the result of the operation, and he was able to lie down straight and stand upright. He was seen two months after he left the hospital, and was then able to walk well and easily, with scarcely any stoop. The operation may be regarded as highly successful, and provided, as he grows, this lowly organised portion of the burn cicatrix remains *in statu quo* and there is further contraction, the same line of treatment may be again resorted to.

BURRA BURRA HOSPITAL, S. AUSTRALIA.

DOUBLE EMPYEMA TREATED BY EXCISION AND ASPIRATION; RECOVERY.

(Under the care of Mr. JOHN I. SANGSTER.)

GEORGE L—, aged two years, had suffered for two weeks from an attack of broncho-pneumonia. At the end of that time the physical signs of the disease were clearing up, some slight dulness and fine moist râles being the only abnormal sounds heard at lower part of right lung posteriorly. During this period no friction sound or any symptom indicating pleurisy was discovered, but as the dyspnœa continued out of all proportion to the physical signs, and the temperature did not fall below 103°, the presence of pus in the pleural cavity was suspected, although a careful daily examination for several days failed to completely decide this point. At length the dulness appeared to have increased, and the breath sounds got less distinct, though the measurement gave a negative result. As the condition of the patient was deteriorating, it was determined to make an opening into the chest, but as a precautionary measure an exploration was made with an ordinary hypodermic syringe. Pus was obtained. The patient was then placed under the influence of chloroform, and an opening was made into the chest in the usual manner, between the eighth and ninth ribs in a line with the angle of the scapula. A considerable quantity of a mixture of serous fluid and pus escaped. A drainage-tube was introduced, and during the time that the wound was left open the pleural cavity was washed out with a small solution of carbolic acid, and, later on, iodine.

The relief obtained by the operation was not encouraging, as the dyspnœa continued almost as bad as before, the temperature fell but little, and the irritable cough continued. At the time of operation the left side was carefully examined,

but no collection could be discovered there. Five days after the operation there seemed to be fluid in the left cavity, and exploration, as before, again proved the presence of pus. The aspirator was used; two ounces were withdrawn. For two or three days there was some improvement; but the dyspnoea gradually returned, and became so severe that another aspiration was made, and six ounces of pus were obtained. After this operation the improvement in patient's condition was marked. He gradually improved; his recovery was retarded by two slight bronchial attacks; diarrhoea was also occasionally troublesome.

More than three months after the last aspiration, and six weeks after the wound on the right side was allowed to close, the child had grown, from a state of great emaciation, stout and rosy, and seemed quite easy in his breathing. The exact state of his chest could not, however, be satisfactorily ascertained, as he would not now submit to an examination. Several cases of empyæma cured by aspiration have been recorded, and it becomes a question whether this should not be first tried, and if necessary repeated, instead of resorting to the more formidable operation in the first instance.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Severe Laceration of Face.—Ataxy in several members of a family.—Sclerotomy for Eyeball Tension.—Elephantiasis of Leg treated by Elastic Bandaging.—Case of Epilepsy treated by Trephining.

THE first meeting of the session of the Clinical Society was held on Friday, Oct. 8th, Dr. Greenhow, president, in the chair. The papers read were of an unusually interesting character, and the President was fully warranted in describing it as a brilliant opening. Dr. Glover called attention to the fact that one of the papers considerably transgressed the ten-minutes rule of the Society, and urged that facts, not theories, were the special study of the Clinical Society. The President, however, replied that the rule, though a valuable one, must be applied with discretion, and that the Society must leave it to him to decide when a paper was unnecessarily prolonged; in the particular case alluded to he had felt that the paper was a very valuable one, and could not with advantage have been shortened—a view in which the members present appeared to concur.

THE SECRETARY read a paper by Surgeon-Major Curran on a Case of Mutilation by a Bear. The bear had bitten his victim's face and destroyed the cheek, one eye, and a great part of both jaws. A photograph of the patient after recovery was shown.

Dr. GOWERS brought forward a series of five cases of Locomotor Ataxy in members of the same family, three of whom were exhibited. The father was healthy, but his brother and two half cousins were insane. The mother had suffered in early life from chorea. The family consisted of nine children: (1) A son, aged thirty-nine, with well-marked ataxy, which commenced at nineteen. He is just able to walk with crutches. There is incoördination in the arms and affection of articulation. Sensation to touch is normal, that to pain on the legs increased. The knee-jerk is lost. (2) A girl, who died of fever at ten years old. (3) A son, aged thirty-five, healthy. (4) A son, aged thirty-three, healthy. (5) A girl, aged twenty-nine, in whom the affection commenced at eighteen. She can now scarcely stand; there is weakness in the legs, as well as ataxy, and also incoördination in the arms. Speech is affected; sensation is normal; the knee-jerk lost. (6) A son, aged twenty-six, perfectly well. (7) A son, aged twenty-three, considerably affected. The disease showed itself at nineteen; he is now scarcely able to walk, with ataxy of both arms and legs, and loss of sensation, absence of the knee-jerk, and affection of articulation. (8) A son, aged twenty-two, reported to be well but found, on examination, to be distinctly affected. Articulation is confluent, there is inability to stand with eyes shut, absence of knee-jerk, and distinct impairment of sensation on the legs to touch. The arms are at present unaffected. (9) A

son, aged nineteen, affected in rather a greater degree than the last, with slight unsteadiness of gait, inability to stand with eyes shut, distinct impairment of sensation to touch, absent knee-jerk, unsteadiness in writing, and confluent articulation. The state of sexual power is doubtful, the patients being all single. Thus of eight members of the family who have reached adult life, five are affected, a daughter and four of the seven sons. The symptoms, allowing for the variations in degree, are similar in all, the chief difference being the marked impairment of the tactile sensation in the two youngest, while in the others, in whom the affection has reached a more advanced stage, it is normal, and except that in one there is hyperalgesia. The only causal influence discoverable is the neuropathic heredity. This form of ataxy was first described as a distinct variety of ataxy by Friedreich, who recorded two groups of cases, and a few other instances have been recorded by Carré and others. Two sisters, evidently suffering from this disease, were shown in 1872 to the Medical Society of London by Dr. A. Carpenter, and in this family a brother has since become affected. Those now shown resemble Friedreich's in the early date of commencement, the affection of the arms, and the interference with speech. They differ from Friedreich's in the number of males affected and in the absence of nystagmus and in the affection of sensation in two individuals. It is noticeable that none have suffered from any pains in the limbs; there is no affection of the iris or of the optic nerve. As in Friedreich's cases, the antecedents were of other forms of nerve disturbances, not of ataxy. The term "hereditary ataxy" seems therefore of doubtful accuracy. Friedreich described the affection of speech as ataxy of articulation, but it does not differ from that seen in other degenerative diseases of the nervous system. The pathological changes were found in two of Friedreich's cases to be in the main similar to those in ordinary ataxy. — Dr. J. ALTHAUS thought that cases of ataxy were more common than usually supposed, and were often confused with paralysis. He had seen more than two hundred cases, but in none of them was more than one member of the family affected, nor could any strict heredity be traced; but in all the cases there was a neurotic tendency observed in one or both parents. Carré's cases were the most remarkable yet recorded. In one instance he states that this form of ataxy was observed in a woman, in her eight children, and in the seven children of one of the daughters—sixteen persons in all—and in three generations. It was remarkable that the pain of ordinary locomotor ataxy was quite absent in this condition, and that the affection of sensation was only slight. He thought that it would be well to follow up the history of those members of this family who were at present unaffected, and also to make careful trial of various therapeutic agents. — THE PRESIDENT had never seen such cases before; and from the striking facts of the early age of the patients when first affected and the complete absence of pain, thought that the disease differed from common locomotor ataxy. — Dr. GOWERS had found that ataxy was very rarely to be traced to hereditary influence; he had stated two years ago that 50 per cent. of patients suffering from it had a history of previous syphilis, and he now thought it more accurate to say that such was the case in 75 per cent. of cases of sporadic ataxy, in all ranks of society. Apparently the disease is the same in those cases occurring in families, as the posterior columns of the spinal cord had been found to be the seat of degeneration. One of the most remarkable facts is that the disease begins at about the age of twenty, and that any members of such a family who are free at twenty-five escape altogether. So marked a feature is this that a recent applicant for life insurance, who had three brothers and sisters thus diseased, but was himself unaffected and much beyond the age of twenty-five, was recommended by him for acceptance as not being prejudiced.

Mr. SPENCER WATSON read a case of Eyeball Tension. Elizabeth M. B.—, a widow and dressmaker, aged forty-six, was operated on by sclerotomy for eyeball tension in 1876, the tension being T 2. After the lapse of four years and a half the eye remains free from excess of tension, and its fellow, though occasionally visited by chromopsia, remains useful. The eye operated on has a staphyloma as the result of the sclerotomy, but this causes no inconvenience and seems beneficial as affording a means of filtration from the anterior chamber to the surface of the eye. The sight continues good up to the present date. — Mr. C. HEATH asked what advantages sclerotomy had over iridectomy. Surgeons were accustomed to see cases of

glaucoma permanently relieved by iridectomy. Some years ago oculists had fully discussed an operation introduced by Mr. Hancock of division of the ciliary muscle, and had not adopted it. By removal of a piece of the iris the secreting surface was reduced, and the tension more effectually relieved.—Mr. S. WATSON replied that sclerotomy, which is a simple section of the sclerotic with a narrow knife parallel with the surface of the iris, was a simpler and less painful operation than iridectomy, and could be done without an anæsthetic, and that as the relief of tensioa was less abrupt there was not the danger of intra-ocular hæmorrhage he had frequently seen occur in iridectomy. But iridectomy was still required for cases of very acute and severe glaucoma. Sclerotomy was not the same as Hancock's operation; the incision was horizontal, not vertical. He did not think the explanation of the value of iridectomy given by Mr. Heath to be correct.

Dr. STEPHEN MACKENZIE related a case of Elephantiasis of the Leg treated by Elastic Bandaging. The patient, a male, aged thirty-three, a native of Rosscar, co. Fermanagh, Ireland, had never been out of Ireland till he came to England for treatment. Worked always as a farm labourer, and was healthy until present disease. Never had syphilis; had never eaten largely of fish. His home was about nine miles from the coast. Ten years ago had an injury to leg, which was much bruised and swollen. About three years after accident the leg was noticed to be larger than its fellow, and from that time to his coming under observation the limb continued to enlarge. About four times a year, with a certain degree of regularity, the leg became acutely worse. Preceded for a few days by nausea, headache, and shivering, the leg became sore and painful, feeling extremely hot, looking red, and steaming. After lasting in this state for about a week, the surface of the leg began to discharge a fluid, clear but of offensive smell. When the fluid escaped he got ease, the heat left the leg, the nausea and constitutional disturbance subsided, and he returned to his usual condition; the limb, however, remained of greater size than before the attack. The limb, when the patient was admitted into the London Hospital in September, 1879, was enormously swollen, presenting several large lobulated masses of oedematous tissue, whilst the surface of the limb was covered by abrasions of the cuticle and papillary elevations. The right leg and scrotum were normal in all respects. There were no enlarged glands. No changes in the blood or urine. He was confined to bed simply for the first month, with slight transient subsidence of the swelling. At the end of that time Martin's bandages were firmly applied to the leg from the toes to the groin. He was kept in bed, with the exception of being allowed to go into the garden for one hour a day. The diminution in the size of the limb from the time the rubber bandages were applied was almost uninterrupted, and very remarkable. All the lobulations subsided; the papillary elevations disappeared. A good deal of fluid exuded from the cuticular abrasions, and the decrease in the limb appeared to be proportionate to the fluid discharged. As the swelling subsided what appeared to be dilated lymphatic vessels could be felt. The patient had no inconvenience from the treatment. During it he had one paroxysmal attack, lasting a few days, in which his temperature rose to 103°, and the limb became hotter than its fellow. Whilst the case probably differed in its origin from the tropical ones, and in the absence of filaria in the blood, the disease reached almost as high a grade as the elephant leg of Barbadoes or India. The case was brought forward to show the good effects of elastic bandaging. There is no novelty in bandaging a limb in this condition, for this treatment is generally adopted alone or combined with other treatment in this disease; but there were not, to the author's knowledge, any published cases in which Martin's bandages have been used for this purpose. The bandages allow of considerable equable pressure, which is kept up as the limb recedes; they are readily applied, and can be washed every day. The results in this case could scarcely have been exceeded by any other treatment, whilst that employed was wholly destitute of the dangers attendant on ligature of the femoral artery. It was found that the swelling recurred when the bandages were removed, so that it is probable that the bandages will have to be worn permanently.—The PRESIDENT asked whether the family history had been carefully inquired into with the view of tracing any possible source of hereditary taint. — Dr. CROCKER mentioned that he had recently had a similar but less

severe case under his care at University College Hospital, which was the sequel of an injury. The elastic bandage was employed, and in a fortnight there was a marked improvement. Although the man was at his work all the time, the reduction in the size of the limb steadily progressed, and the man had not been to the hospital for three or four months.—Mr. A. T. NORTON reminded the Society that at its very first meeting he had recorded a similar case treated by iodide of potassium and tight bandaging. In ten months the man was cured, and when he saw him two years ago there was no return of the disease. The patient continued to wear a bandage.—Mr. GOLDING BIRD had had many examples of elephantiasis from ulcers of the leg among his out-patients that had been greatly relieved by Martin's bandages. He referred to one case in particular of old syphilitic ulceration with this form of chronic dermatitis, in which the reduction of the swelling had been very rapid, but after omitting the bandage for a month the man began to complain again, and he had been compelled to wear it constantly. He considered that the bandage did good by its pressure, and also by keeping the limb in a perpetual Turkish bath.—Mr. E. HART was glad to hear that such a formidable disease was amenable to such a simple treatment, the only really successful case he had ever seen was in Philadelphia nine months ago, in which first the sciatic and then the femoral nerve was stretched.—Dr. DOWSE mentioned a case of elephantiasis which came on five years ago from syphilis for which bandaging, mercury, and iodide of potassium had all been ineffectually tried, but was greatly benefited by the application of the constant galvanic current over the nerves of the limb. The bandages had been given up, and by this treatment alone the patient appeared to be in a fair way to get well.—The PRESIDENT said the cases of chronic dermatitis referred to by Mr. G. Bird were of an entirely different nature from true elephantiasis.—Dr. S. MACKENZIE, in reply, stated that there was no light thrown upon the case by the family history, and that this case was no doubt the result of injury. He had been informed by Mr. Barker that cases of elephantiasis were not so rare in Ireland as in England. He thought that there were all stages between simple chronic dermatitis and elephantiasis to be met with, and no sharp line of demarcation to be drawn. He did not consider nerve-stretching to be a very simple operation; in a case of hydrophobia he had known the operation afford relief to that state, but cause death from pyæmic infection from the wound.

Dr. D. B. LEES and Mr. E. BELLAMY contributed a paper on a case of Traumatic Epilepsy treated by Trephining. S. O—, when seven years old, received a blow on the head from a poker. There was no breach of surface, but the mother found a swelling over the right parietal region. When this subsided no scar or depression of bone remained. The next day he complained of headache, and this symptom persisted more or less until after the operation of trephining. About twelve months after the accident he began to have fits. These occurred at first about once a day, but afterwards more frequently. He attended for several years as an out-patient at the Hospital for Sick Children, Great Ormond-street, but without obtaining relief. On the contrary, the fits became more frequent. It was noticed that they occurred in groups, a period of very frequent fits being followed by an interval, in which he had only about one a day. The periods of exacerbation lasted about three weeks; the intervals of comparative quiet about as many months. Four (if not five) of these alternations occurred during the fifteen months preceding the operation. When the fits were frequent, impairment of grasp in the left hand was always noticed, and he sometimes complained of pain all down the left arm. At such times also the tongue became thickly furred, and his speech (never very clear, apparently from labial paresis) became decidedly more indistinct. In April, 1879 (nearly seven years after the injury), came a period of four weeks, in which the fits were more numerous than ever before, averaging from twenty to thirty daily. In the interval between them he was apparently unconscious. When this period passed away Dr. Ferrier was requested to see the boy in consultation with special reference to the advisability of trephining. He found tenderness on pressure over the right parietal, with loss of grasp in the left hand, and the labial symptoms already mentioned. He advised that trephining should be practised, and that the part of the skull selected should correspond to a spot rather low down in the fissure of Rolando, as the centres involved seemed to be those of the arm and lip, and not of the leg.

The boy was admitted into Charing-cross Hospital under the care of Mr. Bellamy. On the day of his admission he slipped on the waxed floor of his ward and fell, falling on his left knee. He said nothing of this to anyone but his mother, but she afterwards related that he had told her he had had a bad fall. On June 14th, 1879, two days after his admission, Mr. Bellamy trephined, with antiseptic precautions. The "ligne Rolandique" had been previously marked out on the shaven scalp, according to the directions of M. Fort. The spot chosen for operation was about the centre of this line, and was a little lower down than the point indicated by the mother as the site of the original injury. The piece of bone removed was apparently quite normal. It was thought that the dura mater bulged up into the opening made by the trephine. For eight days after the operation the boy progressed very satisfactorily. The temperature gradually came down to normal, the headache vanished, and the wound healed uninterruptedly, and mainly by first intention. Twenty-four hours after the operation the fits ceased, and did not recur for eight weeks. Before the operation he had not for upwards of three years passed a fortnight free from fits. On the ninth day after the operation, however, the temperature began to rise gradually, and in four days reached 104°. There were no rigors. The boy complained of pain and tenderness in the left hip, thigh, and knee. These symptoms continued, with a temperature of 99-100°, during the month of July, and it becoming evident towards the close of the month that the head of the femur was dislocated, Mr. Bellamy excised the head of that bone on the 2nd of August. The pain, tenderness, and rise of temperature still persisted, abscesses formed low down in the thigh and invaded the knee-joint. On the 9th of October it was found necessary to amputate at the hip-joint, which was done with antiseptic precautions. The boy rapidly recovered from this operation, and gained flesh. Eight weeks after the trephining the fits recurred. In seventeen days he had twenty-six fits. If this period represented the expected crisis about three months after the last severe crisis in April, it was unquestionably much reduced in severity. Six weeks of freedom from fits followed. They then recurred, but with much less severity. During the sixteen months that have elapsed since the operation, he has passed to the authors' knowledge thirty-seven, and they believe upwards of forty, weeks entirely free from fits. Four convulsive periods have occurred, but the frequency of fits in these has never averaged more than two or three daily, and he has never been confined to bed on account of them. The authors suggested the following points as worthy of discussion:—1. The advisability of the use of trephine in traumatic epilepsy. They referred to a paper by Dr. Echeverria of New York, published in the *Archives de Médecine* for November and December, 1878, in which no less than 145 cases are cited of traumatic epilepsy treated by trephining. The results in these 145 cases were: cure, 64 per cent.; improvement, 12½ per cent.; no change, 3½ per cent.; made worse, 1 per cent.; death, 19 per cent. Dr. Echeverria maintains that the operation is by no means dangerous in itself, provided that no inflammatory symptoms are present at the time. He refers to cases of many years ago when it was performed more than twenty times on the same patient. 2. The question of the cause of the relief obtained in this case by the removal of a piece of apparently healthy bone. The successful case brought before the Medico-Chirurgical Society last winter by Mr. West of Birmingham was adduced to show that the cause must be the relief of pressure generally, and not any special effect on the motor centres, for in Mr. West's case the lesion and the seat of operation were in the frontal region. 3. The authors wished to inquire whether the periodicity which formed such a marked feature in the convulsions in this boy is usually found in cases of epilepsy due to irritation of the brain cortex. Reference was made to two cases observed at the Hospital for Sick Children, both probably due to lesion of the cortex, in which similar phenomena were observed. 4. They submitted to the surgical judgment of the Society the question of the causation of the osteomyelitis of the femur which followed the trephining. They argued from the antiseptic operation, from the rapid healing, from the boy's satisfactory progress for eight days, from the gradual rise of temperature, from the absence of rigors, and from the exclusive affection of the left hip-joint and femur, that the cause could not have been pyæmic in nature.—Dr. GOWERS suggested that the operation had merely acted

like a seton, which, like other counter-irritations, was well known to be of benefit in some cases.—Dr. BROADBENT had often known epilepsy to be suspended during severe pain or illness, and thought the temporary improvement noticed might be thus explained. He had only seen one case of the kind, and Mr. Heath of Manchester had showed him a patient who had suffered from traumatic epilepsy, and had been benefited by trephining; the fits were, however, beginning to recur.—Dr. LEES, in reply, thought that Dr. Gowers and Dr. Broadbent had hardly sufficiently appreciated the marked improvement in the boy's condition that followed upon the operation.

The meeting then adjourned.

WOLVERHAMPTON DISTRICT MEDICAL SOCIETY.

THE inaugural meeting of the session 1880-81 was held on Tuesday last in the Bell Medical Library. The following officers were elected:—President: Mr. J. T. Hartill, Willenhall. Vice-president: Dr. Totherick. Secretaries: Dr. McMunn; Dr. Joseph Hunt. Committee: Mr. W. H. Hartill, Willenhall; Mr. Sharp, Walsall; Dr. Smith, Bilston; Mr. Dunn, Mr. Vincent Jackson, Mr. Lycett, Mr. Newnham. An address was delivered by Dr. Thos. Barlow, F.R.C.P., Assistant-Physician to University College Hospital and the Hospital for Sick Children, Great Ormond-street, on "The Difference between Children and Adults in their relation to Disease." After the meeting there was a supper, to which nearly all the members adjourned.

Reviews and Notices of Books.

Lectures on Digestion; an Introduction to the Clinical Study of Diseases of the Digestive Organs. By DR. C. A. EWALD, Lecturer in the Royal University of Berlin. Translated by ROBERT SAUNDBY, M.D., Assistant Physician, General Hospital, Birmingham. London: Williams and Norgate. 1880.

"GOOD wine needs no bush:" a laudatory introduction therefore of Professor Ewald's work on Digestion, in its English garb, at our hands is quite superfluous. The German text has already made its way in this country with those familiar with the language, and Dr. Saundby's elegant and accurate translation will secure the work a still wider recognition among English and American physicians and physiologists than could have been possible otherwise. The first two lectures are devoted to a consideration of *ferments*, the questions relating to their intimate character, their significance in the combustion processes of the animal body, their ubiquity, and the possible rôle played by them in the production of the so-called "intra-molecular respiration" (the "dissociation process" of Pflüger) is succinctly and lucidly described. The second lecture ends with a graphic table giving the ferments met with in the animal body and the products resulting from their action; this table we prophesy ere long will become part of the stock in trade of most manuals of physiology. Lectures three and four are devoted to the salivary glands, their histology, innervation, and secreting processes. Heidenhain's experiments, with reference to the effect of the secretion of parotid saliva by stimulation of Jacobson's nerve and the sympathetic, are fully discussed. Professor Ewald thinks as a result of these inquiries we must regard the nerve of Jacobson as governing mainly the separation of water, while the sympathetic presides over the formation of the specific elements of the secretions. Professor Ewald dismisses our old friend "the much-talked-of sulphocyanide of potassium" very contemptuously, regarding it only as a product of decomposition, arising in the cavity of the mouth, probably derived from urea and sulphate of potash. Three lectures are devoted to gastric digestion. Discussing the question what are the causes that bring about the secretion of acid, especially of a

mineral acid, in gastric juice from alkaline blood, Professor Ewald remarks—that a recent “brilliant experiment” of Maly’s has thrown an “unexpected light” on this subject. Both Ewald and Maly, however, seem ignorant of the fact that the separation of acid from an alkaline solution consisting of a neutral and acid salt, both having an alkaline reaction, had been effected experimentally by Ralfe in the laboratory of Charing-cross Hospital, and the particulars of which appeared in THE LANCET, July 4th, 1874, quite three years before Maly’s experiment! Discussing the physiology of the bile, Ewald incidentally directs attention to Rossenbach’s method of testing for bile pigment; it is so simple that it deserves to be universally practised. Icteric urine is filtered and the wet filter paper dabbed with a drop of impure nitric acid, at the border of the paper the play of colours from red to green is developed. On the contrary, with regard to the test for bile acids, we do not think the “Strassbourg method,” recommended by Professor Ewald, superior to that devised by Francis with “sulpho-saccharic acid.” The pancreas, as might naturally be expected, comes in for a considerable share of the author’s attention, but space forbids our doing more than drawing attention to the excellent summary given of all that is known concerning that organ and its secretion. One point, however, we must mention, which has a practical bearing upon treatment of disease, and that is Ewald’s statement that the power of digesting albumen in the pancreatic ferment is destroyed by the action of gastric digestion, so that for therapeutic purposes, so far as concerns administration by the mouth, pancreatic preparations are quite worthless, a view confirmed by Dr. Roberts in the Lumleian Lectures for the present year.

OUR LIBRARY TABLE.

On Removal of the Entire Tongue by the Walter-Whitehead Method; with full details of the operation and after-treatment. By EDWARD LUND, F.R.C.S., one of the Surgeons to the Manchester Royal Infirmary, Professor of Surgery in the Owens College. London: J. & A. Churchill. — Mr. Lund’s object in this paper, which was originally written for the Medical Society of Owens College, is to advocate the plan of excising the whole tongue, which has been systematised, and, in his view, perfected, by Mr. W. Whitehead. The main principles of the operation are the removal of the whole tongue through the mouth by means of scissors only, and the ligature, with silk thread, of the lingual arteries and any branches that may bleed to any troublesome extent. We judge from Mr. Lund’s description that the operation is really formidable, that the hæmorrhage may be profuse and dangerous in more than one way, and that only a bold operator with skilled and trusty assistants should ever undertake it. As by other means, and especially by the use of the wire or thread écraseur, the operation may be robbed of most of its primary and subsequent terrors, we do not think that many surgeons will be found willing to adopt this, a more difficult and dangerous, method.

L’Année Médicale de l’Hospice de la Princesse D. Maria-Amélia à Funchal (Ile Madeira.) Par C. A. MOURRAO-PITTA, M.D., &c. 1871–1879. pp. 23 and 31. — These pamphlets contain a brief report of the work of the hospital to which M. Mourrao-Pitta is attached, during the years 1871–1879. The hospital is devoted to the reception of patients suffering from chest affections. The tables place the patients under the several heads of tuberculosis of the first, second, and third degrees; chronic bronchitis; chronic pleuro-pneumonia; chronic pleurisy; pulmonary gangrene, and chronic asthmatic bronchitis. One hundred and ninety-one cases were under treatment; their occupations, age, and married or single state are given in different tables. There were sixty-six deaths. The object of the reports seems to be to point out that the climate of Madeira is still

charming, notwithstanding the disparaging remarks in regard to it that from time to time appear in the journals. We must leave to those who have made trial of Madeira as a winter residence the corroboration or refutation of M. Mourrao-Pitta’s statements.

Notes on Diseases of Women. By J. J. REYNOLDS, J. and A. Churchill. — This little book contains eighty-six pages, and is said to be “specially designed for students preparing for examination.” In the short space stated it treats of diseases of the uterus, vagina, and vulva. It can, however, be regarded as little else than an index to larger works upon the subject. It cannot teach diseases of women, though it may be an aid to the memory of those acquainted with the subject. We can see no reason for the publication of such a work. On the other hand, there are many reasons against it, for such books aid cramming (which frustrates the object of examinations), and encourage ignorance of such subjects as they treat.

Science. Vol. i., No. 2. Sept. 11th, 1880. — The current number of this young and well-conducted journal contains a very long and interesting article upon the photophone, by Mr. Alexander Graham Bell. The principle of this instrument is, that a beam of light is reflected upon a mirror diaphragm, which is set in motion by the voice or other means. The concentrated ray is then reflected so as to affect a piece of selenium in a telephonic current, which by its varying conductivity acts intermittingly on the diaphragm of the telephone, and thus in the usual way reproduces the sound. The paper is illustrated by many drawings, and is well worthy of perusal.

The *Leisure Hour*, the *Sunday at Home*, the *Girls’ Own Paper* (Religious Tract Society) are serials which deserve the success they seem to have achieved. They supply a literature useful of its kind and wholesome in its tendency, and which compares favourably with much that is issued avowedly for the benefit of the religious public and our juvenile population. The October part of the last-named publication contains an article, with illustrations, on a subject to which we have repeatedly called attention—namely, the urgent need for the provision of seats for shop-women. The device suggested in the article referred to, though no doubt ingenious, appears to require to be submitted to the test of further experience before it could be confidently recommended for universal adoption.

We have also received the following:—*Professional Book-keeping.* By W. J. Gordon (Wyman and Sons). *Illustrated Guide to Blackpool.* A new edition of the *Familiar History of Birds.* By the late Dr. E. Stanley (Longmans). *Dickens’s Dictionary of London.* *Picturesque Tourist of Scotland* (A. & C. Black). *The Englishman’s Illustrated Guide-book to the United States and Canada* (Longmans). The Fourth Edition of the *Nature and Treatment of Syphilis.* By Dr. C. R. Drysdale (Baillière, Tindall, and Cox). *Introductory History of England.* By W. M. Lupton (Longmans). *Journals and Journalism.* By John Oldcastle (Field and Tuer); &c. &c.

New Inventions.

A NEW OPERATING-TABLE.

WHEN making our inspection of the new Edinburgh Royal Infirmary, we were much struck by Professor Annandale’s new operating-table, and we have pleasure in laying before our readers a representation and description of the same. This table has been constructed at Professor Annandale’s suggestion, with a view to combine several arrangements already in use in other hospitals. By means of two screws, D D, the portions A B, the body of the table, can be steadily elevated or depressed, together or separately,

while the patient is on the table. The portion A was specially designed in order to allow the head to be placed in the dependent position during operations on the mouth, throat, ace, &c. (see Professor Amundale's paper in THE LANCET

of March 8th, 1879); and the two small trays, *c e*, which can be folded down, are found to be very useful for placing, convenient to the operator's hands, a small basin containing carbolic solution, for dipping instruments into and carrying

out other Listerian precautions. Castors covered with vulcanised india-rubber have been added to the legs since the drawing was taken, which render it easy of movement. The table has been made by Archibald Young, surgical instrument maker to the Royal Infirmary, 57, Forrest-road, and 58, North-bridge, Edinburgh.

IMPROVED REGULATING DIGITORUM.

A MODIFICATION of the dumb piano has been contrived by Messrs. Horn, of Elgin-road, Croydon, which is designed to strengthen the movements of the fingers by rhythmical exercise. It consists of a series of five or more piano-keys, the resistance of which can be nicely regulated from an ounce to a pound, or more if required, and the degree of resistance is shown by an index at the side. Another improvement consists in a means of regulating the touch of the keys from one-eighth to seven-eighths of an inch, as required for the purpose of exercising the muscles more fully. Messrs. Horn, in the wording of their prospectus, seem to suggest rather more power for the instrument, as a means of restoring strength, than it can justly claim; but as a contrivance for facilitating muscular exercise of the fingers it is certainly a useful mechanism, and as such has been found of practical value.

THE LADIES' SANITARY TOWEL.

THIS consists of soft wool, which has been treated with a disinfecting substance. It appears to be well adapted for the purpose which it is intended to fulfil, but while the price charged for it remains at three shillings a dozen, we cannot expect it to come into common use. This is a misfortune, for this towel has advantages, not the least of which is that it must be destroyed immediately after use. The towels are manufactured by Messrs. Southall Brothers and Barclay, Birmingham.

THE IMMEDIATE TREATMENT OF STRICTURE OF THE URETHRA.

To the Editor of THE LANCET.

SIR,—In your issue of the 2nd inst. appears a letter from Mr. Horace Manders, in which he alludes to my letter to you on the subject of the treatment of stricture by the "immediate plan." Mr. Manders seems entirely to misapprehend the object with which my letter was written; it was not written with the view of contrasting one plan of operative procedure with another, but was written solely

with the view of vindicating Mr. Holt's operation, so far as my experience, by no means a limited one, goes, from the vague, serious, and unsupported charges so unhesitatingly brought against it. Were it my object to contrast different modes of operative procedure, I might refer to two fatal cases (the patients being dear personal friends of my own) resulting on external urethrotomy, the operation having been performed in one case by the late Mr. Hutton of this city, a surgeon second to none, and in the other by no less a person than the late Professor Syme. I could also refer to at least one fatal case resulting on internal urethrotomy, the instrument employed having been Maisonneuve's, and the operator being one of our most skilful hospital surgeons.

I am, Sir, yours, &c.,

RAWDON MACNAMARA,

Surgeon to the Meath Hospital, and Senior Surgeon to the Westmoreland Lock Hospital.

Stephen's-green, Oct. 9th, 1880.

To the Editor of THE LANCET.

SIR,—I observe in THE LANCET of the 2nd inst. a reference by Mr. Teevan to a case of mine in which death followed the above operation. Mr. Teevan assumes that because the patient had dropsy he suffered from renal disease. On referring to my notes, I find that such was not the case. He had ascites from diseased liver, and as a complication a very tight stricture. The introduction of a catheter was extremely difficult and accompanied by great pain, and I thought it better to split than subject him to continual irritation. I am bound to say that I do not attribute the death to the operation; on the contrary, I believe he thereby obtained much relief.

I have several times performed Holt's operation, and my experience, so far as danger to life is concerned, is decidedly favourable. I feel it the more necessary to state this distinctly, as, for other reasons which I need not here go into, I have abandoned the operation in favour of internal urethrotomy. (Vide THE LANCET, vol. i., 1878, p. 200.)

I am, Sir, yours truly,

Liverpool, Oct. 6th, 1880.

C. E. LYSTER.

GLASGOW SOUTHERN MEDICAL SOCIETY.—At the thirty-seventh annual meeting of the Glasgow Southern Medical Society, held on October 7th, the following office-bearers for the session 1880-81 were appointed:—President: T. F. Gilmour, L.R.C.P. Ed. Vice-President: Neil Carmichael, M.D., F.F.P.S.G. Treasurer: E. McMillan, L.R.C.S. Ed. Secretary: William Carr, M.B., L.R.C.S. Ed. Editorial Secretary: William McFarlane, M.D. Seal-Keeper: Alex. Napier, M.D. Court Medical: John Niven, L.F.P.S.G., Convener; A. L. Kelly, M.D.; Eben. Duncan, M.D.; Jas. Stirton, M.D.; Robt. Park, L.F.P.S.G. The following gentlemen, with the office-bearers, form the council: A. J. Hall, M.D.; Archd. Pearson, M.D.; Wm. Wilson, L.R.C.S. Ed. William Carr, M.B., Secretary.

THE LANCET.

LONDON: SATURDAY, OCTOBER 16, 1880.

BOTH the aspect and the actual position of affairs at Guy's Hospital have changed since last we discussed the situation, its duties, and its probabilities. Just as we were going to press on the 7th inst., the Governors held a Special General Court, and passed resolutions condemning the action of the medical staff, and calling upon Dr. HABERSHON and Mr. COOPER FORSTER to resign. The terms in which the Governors embodied their conclusions and determination are so remarkable that we reproduce them. "Resolved—(1) That it is essential to the well-being of the hospital that the medical staff and nursing department should work in harmony. (2) That the medical staff having persisted in ignoring the matron appointed by the Court, and confirmed in her appointment after patient investigation of all complaints against her, while she is on her part willing to submit herself obediently to the orders of the several physicians and surgeons in all matters directly affecting the treatment of any patient, this Court finds that it is the attitude of the medical staff which impedes the harmonious working of the hospital. (3) That Dr. HABERSHON and Mr. COOPER FORSTER having made themselves responsible for a circular in which they refuse the means offered them by the Court for bringing all complaints before it, and impute to the Governors that they knowingly persist in a mischievous system, are hereby required to resign the posts which they hold in the hospital.—HENRY H. GIBBS, President of Guy's Hospital." Let us see what all this means.

The first resolution has the literary merit of going straight to the root of the matter, and making the issue perfectly clear. The Governors regard the medical staff as one element of the hospital system, and the "nursing department" as another, and they require that the *two* "should work in harmony." Here lies the germ of the whole contention, and whatever may be done to gloss over the surface of matters, there can be no final settlement of the real issue raised until it is recognised that "the medical staff" and "the nursing department" of a hospital are *not* two departments which "should work in harmony," but that the "nursing department" of a hospital stands in precisely the same relation to the medical staff as the dressing, the pharmaceutical, or the surgical-instrument "departments." In short, it must be seen and felt by all concerned that, inasmuch as a hospital is *throughout* an establishment for medical treatment it—that is, the institution as a whole—must be organised, not in "harmony" with, but in subserviency to, the medical authority. Nursing is not, and never can be, a separate branch of skill or a specialty. It is an integral part of treatment; and medical committees which for the sake of peace are tacitly allowing the "nursing departments" at other hospitals to be regarded as distinct, and striving, from amiable but short-sighted motives, to work in "harmony" with them, are practically surrendering a principle, and preparing the way for a cata-

strophe which in the interests of the sick poor, not less than of science, ought to be averted.

The second resolution is one chiefly affecting the details of the local controversy at Guy's, and does not call for general discussion. Whether or not the matron of that institution is "willing to submit herself obediently to the orders of the physicians and surgeons in all matters directly affecting the treatment of any patient," is scarcely a question with which the profession has any concern. It is not of the *personnel* of this particular establishment we desire to speak, but of the system at work there, and the organisation as a whole. The matron may be docile, but the position she occupies as the head of a separate "department" is untenable. The medical interests of the poor and of the institution cannot be satisfied by any concession on *her* part. Unless the service is so changed that the medical men shall have direct control of the nursing to which *their* patients are subjected, and by which, in a large measure, diseases are "treated," it is impossible to regard the position of affairs with confidence or even complacency. The nurse is the agent of the physician or surgeon in charge of a case. She is as much his instrument, and the interests of cure require that she should be as completely under his control, as the drug prescribed by the physician, or the knife in the hand of the surgeon. If he directs that a patient shall be kept in the recumbent posture, no matron must be empowered to give any contradictory order, and no rule can be allowed to stand in the way of the special directions of the physician being carried out. So, likewise, nurses must not be removed from ward to ward, either at the caprice of the matron or in obedience to any rule of rotation, so that the services of a nurse trained by a particular physician or surgeon, and familiar with *his* system of nursing, whatever that may be, shall be lost to the medical officer and his patient. These are fruits of the "nursing department," and it must be uprooted. The attempt to work in harmony with it is vain, because the system is, in itself, *mischievous*.

The third resolution embodies the judgment of the Court of Governors upon the letter of Dr. HABERSHON and Mr. COOPER FORSTER, and the penal sentence which, in its wisdom, that Court saw fit to pronounce. The following is the text of the letter which has given such dire offence.

*To the President, Treasurer, and Governors of
Guy's Hospital.*

MY LORDS AND GENTLEMEN,—We have carefully considered the Report of the Governors' Committee, and the proposals which you have made to us in accordance with its recommendations. We beg to thank you for the further explanations which we have received from the Treasurer through Dr. Habershon, and to express our appreciation of the trouble taken by the Committee. We regret, however, that we are obliged to decline the proposition which you have made. We entirely disapprove of the system of nursing which the Treasurer introduced last November, without consultation with us, without our sanction, and even without our knowledge. We told the Treasurer in December, and the Court of Governors in February last, that the new Matron was unfitted for her post, and we asked for her removal. We then warned you of the evils which would ensue if our representations were disregarded. We need not say how lamentably these fears have been realised. Our patients have suffered, the discipline of our School has been impaired, the good order and harmony which ought to

exist has been gravely disturbed, and the authority of the Treasurer has been thrown away. Worst of all, the cherished reputation of Guy's Hospital is in jeopardy. We should be most happy to aid the Taking-in Committee with our counsel, but so long as the present Matron is maintained in office, and so long as the Treasurer continues the course of action which has led to our present disasters, we have no hope of real improvement, and we cannot consent to take part in a system which we and you alike know, by the unhappy experience of the last few months, to be in every respect mischievous.

We cannot but hope, in justice to the Governors, that they will even now take the obvious and necessary steps to restore the prosperity and harmony of last October. If our unanimous and repeated protests are disregarded, we must publicly record the facts which abundantly justify our action, and leave the responsibility of present and future evils upon the Treasurer and Governors. We shall continue to perform our duties to the utmost of our power; we shall still do our best to obviate the consequences of ill-advised action; and we shall wait with confidence for better counsels to prevail.

We are, my Lords and Gentlemen,

Your obedient servants,

(Signed on behalf of the
Medical Staff.)

S. O. HABERSHON,
Sen. Phys. Guy's Hosp.

J. COOPER FORSTER,
Sen. Surg. Guy's Hosp.

Guy's Hospital, Aug. 13th, 1880.

The medical faculty have, it appears, withdrawn this letter. At a full meeting of the medical and surgical staff, held on Saturday, Oct. 9th, it was unanimously resolved:—"1. To request the Governors' permission to withdraw the communication dated August 13th, 1880, and to express regret that a sentence contained in it should be open to the construction which has been put upon it; and further, to offer their assurance that it was not intended by the staff to impute that 'they (the Governors) knowingly persist in a mischievous system.' 2. That having heard through Dr. HABERSHON that representatives from the staff are to form an integral part of the Sub-committee of Governors, the staff are prepared to send representatives accordingly. 3. That as Dr. HABERSHON and Mr. COOPER FORSTER signed the communication of August 13th on behalf of the staff, this meeting feels the staff is collectively responsible for it." There is, happily for the honour and dignity of the medical staff, no foundation whatever for the statement in a newspaper report that the medical staff expressed a hope that, "under the circumstances," the Governors would rescind their resolution calling upon the senior physician and surgeon to resign. Disunion would have been a fatal evil; but here again we have the satisfaction of knowing that the several members of the staff have pledged themselves to stand together and to be bound by the action of their seniors in their name and on their behalf. They, in fact, placed their resignations in the hands of Dr. HABERSHON and Mr. COOPER FORSTER, to be used in the event of those gentlemen being compelled to retire. It would, indeed, have been a deplorable *finale* to what promised to be a manly assertion of the true claims made by the medical profession in the interests of the sick poor, if those to whom we all look with respect and confidence as standing boldly in the breach, had surrendered, or even faltered in their steadfastness at the moment of victory. The cause in which they are engaged is not their own, nor are their personal interests to be regarded as paramount. Humanity imposes upon them the duty of speaking and

acting in the behalf of hospital physicians and surgeons throughout the country. It is comprehensible that the staff may prefer to withdraw a phrase which, as they allege, has been misinterpreted, but we must confess our inability to understand why the letter as a whole has been withdrawn. It was, as our readers will see, a manly, straightforward, and good letter, embodying the conclusions at which everybody who knows anything of this lamentable business must have arrived independently. The Governors, in their statement, did not quote correctly the sentence to which they took exception. They charged Dr. HABERSHON and Mr. COOPER FORSTER with having imputed to them that they persisted in maintaining a system which they, the Governors, knew to be in every way mischievous, whereas what Dr. HABERSHON and Mr. COOPER FORSTER actually wrote was: "We cannot consent to take part in a system which we and you alike know, by the unhappy experience of the last few months, to be in every respect mischievous." If there is any sting in this sentence, its virulence must be entirely due to its veracity. Why it should have been withdrawn we cannot even guess. If the truth may not be spoken in any letter addressed by the medical staff to the governors of a hospital, the relation of these two authorities needs to be entirely revised.

As the matter now stands, we assume that an attempt will be made to carry on the business of the hospital by means of what purports to be a joint administrative committee. Such a committee, as Mr. LUCAS has opportunely pointed out, ought, in accordance with the express wishes of the founder of Guy's, to be constituted, in part at least, of medical men. THOMAS GUY, by his will, nominated four physicians—namely, Drs. RICHARD MEADE, THOMAS CROW, FRANCIS FOUQUIER, and EDWARD HULSE, as a Committee of Management. By the process of self-election—a destructive arrangement at the best—the medical element has been entirely excluded from the Committee of Management! This is a matter which ought certainly to be brought under the notice of Parliament. In spirit it contravenes the terms of the founder's will, and transgresses the fundamental principle which is supposed to underlie the policy of the Charity Commissioners. An essentially *medical* institution cannot successfully or consistently be administered without the presence of a *medical* element on the Committee of Management. It may be expedient to give the arrangement by which a medical element is to be introduced into a "Taking-in Committee,"—a half-hearted and round-about way of making a concession—the trial asked for; but we are doubtful of success. It ought at least to be a condition of the agreement that the Governors shall acknowledge their error in trying to rule the hospital without the medical staff, and to treat the physicians and surgeons as their servants instead of the principal authorities in the charity. We cannot claim a lower status than this for the profession in relation to institutions established *solely* for a curative purpose, whether they be hospitals for the sick or asylums for the insane. And, we are convinced, no lower status can be assumed by any medical staff without a sacrifice of usefulness and self-respect.

A RECENT outbreak of nervous disturbance in Italy, which has been described in the *Annales d'Hygiène* by M. LÉON

COLIN, indicates that the conditions which gave rise to some of the most remarkable epidemic phenomena of the Middle Ages are not yet extinct in the country in which they were then chiefly prevalent. On Dec. 11th, 1878, the governor of the district of Tolmezzo informed the Prefect of Udine that for three months some forty females, living in the commune of Verzegnis, had been attacked by religious mania. In consequence, Drs. FRANZOLINI and CHIAP were delegated to examine the outbreak. From their report it appears that the first case was in the person of a woman named MARGUERITE VIDUSSON, who had been the subject of simple hysteria for about eight years. In January, 1878, she began to suffer from convulsive attacks, accompanied by cries and lamentations. She was regarded as the subject of demoniacal possession, and on the first Sunday in May was publicly exorcised. Her affection, however, increased in severity; the attacks were more frequent and more intense, and were especially provoked by the sound of church bells, and by the sight of priests. Seven months later, three other hysterical girls became subject to "convulsive and clamorous" attacks. Here, again, an attempt was made to get rid of the supposed demon. A solemn mass was said in the presence of the sufferers, but was followed only by a fresh outbreak. At the time of the visit of the delegates eighteen were suffering, aged from sixteen to twenty-six years, except three, whose ages were respectively forty-five, fifty-five, and sixty-three years. Similar symptoms had also appeared in a young soldier on leave in the village.

During the attacks the patients talked of the demon which possessed them, stated the date on which they were seized by it, and the names of the persons who were possessed before them. Some boasted of being prophetesses and clairvoyants, and of having the gift of tongues. In proof of the latter they pronounced incomprehensible sentences which they affirmed to be Latin or French. In all the sound of church bells caused attacks, and religious ceremonies appeared not only to aggravate the disease in the sufferers, but also to cause its extension to those not previously attacked. The reporters referred the outbreak to pre-existing hysteria, aggravated by the fanatical zeal of certain preachers, and to the frequency and exceptional impressiveness of the religious services which were being held as a means of cure. Their effect was to recall to the memory of the hysterical women the legends of demoniacal possession and of sorcery, and the exorcism of the priests deepened their conviction as to the nature of the affliction. Dr. FRANZOLINI draws special attention to certain old establishments long of repute for the efficacy of the exorcisms practised at them. He cites especially the sanctuary of Clanzetto, an odious vestige, as he terms it, of the barbarism of the Middle Ages.

M. COLIN points out that the soil was particularly favourable for the development of an epidemic of this nature. The population of Verzegnis is backward in education, and most superstitious, and functional nervous diseases are common among them. Dr. FRANZOLINI has, however, ascertained that they possess a practical immunity from alcoholism and from pellagra, and also from diseases due to general insanitary conditions. He appears to be inclined to ascribe some share in the production of the disease to an

obscure pathological influence derived from the French race, since he notes that the inhabitants pronounce the letter "r" as it is pronounced in France, and not as in Italy—the suggested inference from this circumstance M. LÉON COLIN is naturally unable to discern. It appears, further, that the inhabitants of the village are a good deal cut off from intercourse with the adjacent country in consequence of comparative inaccessibility, and the frequent interruption of communications by storms and floods. Moreover, craniometric observations on twelve of the inhabitants seem to show that the brachycephalic form of skull predominates, and that the development of the cranium is slightly below the average.

M. COLIN points out, with much truth, that the relative sequestration of the inhabitants of a town must tend to favour the spread of such a nervous malady, if it does not assist in its production. The reciprocal impressions of the inhabitants are little varied, and hence, in spite of differences in age and social position, the members of the community come to bear a close mutual resemblance in psychological constitution. Consanguineous marriages will be common in such a population, and will contribute to the deterioration of the masses, and to the development of any common morbid predisposition. If such a predisposition results, in one individual, in actual disease, many others are probably not far from the same morbid state, ready to undergo fuller development by imitative contagion.

The epidemic at Verzegnis has proved extremely obstinate. Since the commissioners visited the place, new cases have occurred, which have rendered energetic measures necessary—even a military occupation of the district (!)—while seventeen of the "possessed" have been compulsorily removed to the hospital at Udine. Such an epidemic constitutes a rare event in modern Europe, but it reminds us closely of some historical epidemics with which all are familiar. Even in our own day, in some backward races, as of Norway and New Caledonia, similar outbreaks have been observed.

THE Introductory Addresses in the provinces bear a very favourable comparison with those of the metropolis, and only confirm that consensus of advice and opinion on which we remarked as a feature of the London Introductory. There is no royal road to medical knowledge or success. The provincial teachers agree with the London ones that only on the basis of a good general education can a solid medical education be founded; and that the most vital subjects of study in real medical education are Anatomy and Physiology. On the whole, there seems a tendency in the mind of teachers to attach more importance to Physiology, and perhaps less to very minute and detailed Anatomy. Surgical, regional, prominent, and medical Anatomy, all are agreed, should be severely and soundly learnt. That Pathology cannot be understood apart from Physiology is one powerful reason for attention to this subject; but there is another, in the fact alluded to by Dr. WATERS, of the Liverpool School of Medicine, that it is daily more and more taught in schools, and will, in its great facts, become part of the common knowledge of educated people; and in these days of school boards who is to remain uneducated? We note Dr. WATERS'S words on Anatomy, and on the provision for its teaching in Liverpool, with great satis-

faction. "It [Anatomy] lies at the root of all your studies, and you will find in this school the completest means and opportunities for acquiring a practical knowledge of it..... You will find the study of it not only essential in order to pass examinations, not only in reference to the study of disease and accidents, but also of the highest value as a training for the mind." Students of the first and second year especially, who are still in the happy position of having no experience of unsuccessful examinations, might do worse than make a large-sized copy of these words, and place them over their mantelshelf, and students who have had such experience will find the best security against a repetition of it in a similar device.

Dr. GWYNNE, of Sheffield, in a very able address, drew attention to the special advantages of the Sheffield School. He was severe in his reflections on Oxford, hoped much from the lately-created Victoria University of Manchester, and, while admitting the good done by the University of London, maintained in manly language that "it failed in the most valuable duty of a university—viz., *teaching*." He specially recommended the study of physiology, and the institution of a preliminary scientific examination, so as to lighten the overcrowded curriculum. At Leeds, too, Mr. CHARLES J. WRIGHT advocated, like Dr. ORD, making the natural sciences part of the school schedule. Mr. WRIGHT also touched on the question of pupilage to a general practitioner. Though there is some difference of opinion as to where this should come in the career of a student; there is a growing tendency to believe, what is only too obvious, that some great lessons of practice can only be learnt properly in the school of practice itself. Mr. WRIGHT would place this pupilage in the period just succeeding the Primary Examination in Anatomy and Physiology. Like Dr. GWYNNE, he spoke in favourable terms of the Victoria University, and expressed a hope that a union might ere long be effected between the College and their own School of Medicine. Professor BARTLETT, at Birmingham, though indulging in a somewhat gloomy style as to the political and social disadvantages of the position of the medical practitioner, became more cheerful at the close, and said that the general practitioner was the backbone of the profession, the man to cope with difficulties of every kind in every department of general and special practice, and honoured in his district as those in special practice rarely were.

Annotations.

"Ne quid nimis."

THE NURSING QUESTION AT THE WESTMINSTER HOSPITAL.

FOR the past few years the Westminster Hospital has been nursed by the Westminster Training School for Nurses, an institution founded by the late Lady Augusta Stanley in 1874. Owing to certain disagreements between the hospital authorities and the committee of the home and their servants, it has been found necessary to cancel the standing agreement, and substitute for it another. We have this new agreement before us, and call attention to it because it is most important to watch vigilantly the various developments of the "nursing department." The main provisions of

this agreement are as follows:—The nurses are to be under the charge and authority of a "lady superintendent," to be selected by the home, and appointed by the hospital. This person is to be paid by the home, but is to reside in the hospital, and in addition is to discharge the duties of matron of the hospital without salary. The committees of the home and of the hospital are annually to appoint three of their number who shall form a "nursing joint committee," and "all complaints with respect to matters in the hospital under the control of the lady superintendent, whether as lady superintendent or matron, shall in the first instance be made to her, and if the complainant be not satisfied, the complaint may be made to the house committee, or to the committee of the home, to be by them referred without discussion to the nursing joint committee, whose decision shall be final." Should any questions arise which are not thus provided for, they are to be settled by three referees, one to be nominated by each of the two committees, and the third by the two thus chosen. "The lady superintendent shall not be removable except by common consent of the hospital and the home, and in the event of any difference arising on this subject the matter shall be referred to the referees." The permanent staff of nurses is to be not less than twenty-six in number, and the home may send to the hospital for training probationers not exceeding twenty-five at any one time. The other clauses in the agreement refer to the financial arrangements. Viewing the matter from an outside, and impartial, standpoint, we think this agreement contains within itself endless opportunities for disagreement. The only possible chance of its working well is that a wise woman should be appointed lady superintendent, and that there should never be any occasion to refer to the agreement. Leaving out of sight minor points, there are several of the provisions to which most serious objection must be taken. First of all, there is the introduction of an outside authority not in any way officially connected with the hospital; for although the lady superintendent is to perform the duties of her office "subject to the general control of the house committee of the hospital," that committee cannot select her, cannot dismiss her, does not pay her, and may not consider any complaint brought against her from any source whatsoever. Its "general control" over her is therefore a mere figure of speech, a delusion, and, we fear, a snare. But this is not the worst of the matter, for the duties of matron are to be discharged by this lady superintendent, over whom the hospital authorities have no direct control; and yet these duties have nothing whatever to do with the nursing of the hospital; the hospital authorities have actually delegated their duty of choosing their own matron, and if perchance she and the cook or any of the servants disagree, the matter has to be referred to a "nursing joint committee." How is it possible that any decisions of an outside authority can be final on questions relating purely and solely to servants of the hospital? The next fundamental blot in this agreement is the total ignoring of the claim of medical officers of hospitals to control the nursing of the patients for whose welfare they are responsible. The staff are specially precluded from the appointment of referees, and the only point on which they are to be consulted is the dismissal or removal of ward sisters; but unless they agree with the lady superintendent, the matter is to be referred to the "nursing joint committee," so that their authority here is nominal rather than real. It is not difficult to trace the real purport of the agreement; the one object attained by it, whatever may have been in view, is the conversion of the hospital into a training school for nurses in connexion with the home. As many as twenty-five women may be sent to the hospital regularly for the purposes of training only, while only one more than that number of trained nurses has to be provided

as the permanent establishment; and at the same time the home is to be paid more highly than formerly for its services. Against this we fail to find one single advantage to accrue to the hospital. None are so interested in improved nursing as doctors, but the fundamental principle of all good nursing is that, like the other treatment, medicinal and dietetic, it shall be directed and controlled by the medical men in charge of the case.

QUEEN'S UNIVERSITY IN IRELAND.

THE annual meeting of Convocation of the Queen's University in Ireland was held on the 7th inst., presided over by Sir Robert Kane, Vice-Chancellor. The report of the annual committee for 1879-80, which was adopted, expressed an opinion that the University Education (Ireland) Act of 1879 was unfair to the Queen's University and its graduates and undergraduates, now numbering nearly 3000. The committee trusted that Her Majesty's Government would reconsider the matter, and make such changes in the educational arrangements of Ireland as would leave to the Queen's University a continued separate existence. The Senate having nominated Sir Robert Kane, F.R.S., as Vice-Chancellor in the room of the late Sir Dominic Corrigan, the place which he held on the Committee as an ordinary member was vacated, and Dr. O'Keefe, of Cork, was unanimously elected to the vacancy. A resolution in reference to the dissolution of the University and urging that an appeal should be made to the Government to reconsider its position, as alluded to in our issue of last week, was unanimously adopted; it being a further instruction that the Committee of Convocation should seek the co-operation of the Graduates' Association at the Queen's Colleges and in London, in appointing a deputation. Mr. R. J. M'Mordie then moved a series of resolutions, to the effect that without reference to the demands for endowed sectarian universities or colleges, Dublin University should occupy in relation to any new university the same position as the Queen's University; that the existing non-sectarian colleges—viz., Trinity College, Dublin, and the Queen's Colleges—should be affiliated colleges in a non-sectarian teaching university; that by additional endowments, or an adjustment of existing endowments, they should have similar advantages as regards professorships, residences, fellowships, and exhibitions; and that a deputation be appointed to submit the views of Convocation to the Prime Minister and the Chief Secretary for Ireland. These resolutions, however, after a little discursive argumentation, were withdrawn, and the proceedings terminated. We may add, that there is little doubt that the legislation of the late Government in reference to university education in Ireland has not been successful. It has not satisfied anyone; it has disappointed the friends of the Queen's University, and it has only partially pleased its enemies. It is, indeed, notorious that some of the most influential members of the Senate of the new University have joined in open condemnation of the Queen's Colleges; although an assurance was publicly given by the late Government that they would not be injured.

UNCERTIFIED CAUSES OF DEATH IN LONDON.

THE present unsatisfactory state of registration law notwithstanding, a good deal of unfounded indignation was recently expressed at a special meeting of the Sanitary Committee of the St. Pancras Vestry, with reference to the statement of the Medical Officer of Health, that the registrars of births and deaths in London are in the habit of registering deaths in a wholesale manner without a medical certificate. We have continually insisted that the State, which compulsorily imposes upon all registered medical practitioners the duty of furnishing gratuitous certificates of the causes of the

deaths of their patients, is bound to provide some means for obtaining satisfactory and scientific evidence of the causes of other deaths—namely, cases in which no registered practitioner has been in attendance on the deceased, and in which no inquest is held; and we further maintain that effectual means might be adopted for securing this end, which, instead of increasing the number of inquests, would render unnecessary a large proportion of those now held. Such a reform, however, which is intimately bound up with the impending reform of the laws governing the appointment and duties of coroners, will rather be retarded than assisted by such unfounded charges as those alleged to have been made by the Medical Officer of Health of St. Pancras against the registration system generally in the metropolis, and especially in St. Pancras. According to the Registrar-General's Weekly Returns, it appears that during the thirteen weeks ending the 2nd inst. only 213 out of the 19,426 deaths registered in the whole of London, or scarcely more than one per cent., were uncertified. A very large proportion of these were cases of infants who died within a day or so of birth, and whose mothers had only been attended by a midwife, and had not called in a registered medical practitioner; of the remainder, a considerable proportion were cases in which the deceased had been attended either by an unqualified practitioner, or by the unqualified assistant of a registered practitioner. We should hail with satisfaction the inauguration of a system which would secure satisfactory certification of all causes of death, but considering the state of the law we are astonished at the small proportion of uncertified deaths in London, and can see no ground for complaint as to the manner in which the law is carried out. As regards registration in St. Pancras, we are informed on good authority that only two of the 1245 deaths registered within that district during the three months ending last quarter were uncertified. We agree with the Vestry Clerk, that there must be some great mistake in the matter to account for the charge of wholesale registration of uncertified deaths, whether in St. Pancras or in any other part of London. As a matter of fact, the proportion of uncertified causes of death is smaller in North London (including St. Pancras) than in any other part of the metropolis. The largest proportion of uncertified deaths occurs in South London, especially in Southwark and Woolwich.

CONVULSIONS FROM ABSINTHE.

MANY of our readers will remember the researches of M. Magnan on absinthism. He stated that the administration to an animal of a relatively small quantity of essence of absinthe causes convulsive attacks closely resembling those of epilepsy, presenting loss of consciousness, tonic and clonic spasm, with tongue-biting, involuntary evacuations, and subsequent coma. He maintained that such attacks may occur in man under the influence of great or prolonged excesses in absinthe liqueur, and, in support, he adduced cases from his own observation, and from that of others. These facts have not, however, been accepted as conclusive by all subsequent workers. Bohm and Kobert, for example, have maintained that the dose of absinthe which has to be given to a mammal to cause convulsions is so large that it is difficult to admit that a sufficient quantity is ever taken by man. They further maintain that the essence of aniseed, which is always added to the absinthe liqueur, possesses deleterious properties, and that its effect is attributed wrongly to absinthe. M. Dujardin-Beaumetz administered large doses of absinthe to pigs, but never witnessed convulsions as a consequence, although the dose amounted to one or two grammes per kilogramme of body weight.

Further doubt has been thrown upon the conclusions of M. Magnan in a recent communication of M. Lance-reaux to the Académie de Médecine. In some cases of

chronic absinthism to which he alludes, in which convulsions were supposed to be due to the toxic agent, an autopsy demonstrated the existence of chronic meningitis sufficient to explain the occurrence of the convulsive attacks. In some cases of acute absinthism relied upon by M. Magnan, the attacks, according to Lancereaux, resembled those of hysteria rather than of true epilepsy, and he cites, in support of the view, five cases which have come under his own notice. In one case a regular absinthe-drinker had long-continued attacks, and was found by M. Lancereaux in a well-marked hysteroid seizure, unconscious, with opisthotonos and violent irregular movements. Neither coma nor stertor followed. In the four other cases the character of the seizures was the same. Nevertheless it remains true that in some of the cases recorded by M. Magnan the attacks were of a true epileptic character, and it is quite within the range of pathological probability that the same cause should give rise in some individuals to hysteroid, and in others to epileptoid seizures. The deleterious effect of the agent is almost as grave in the one case as in the other, for recurring hysteroid attacks in men constitute almost as serious a disease as genuine epilepsy. The subject is one of more pressing moment in France than in this country, but even here we cannot afford to disregard it, since "Absinthe Suisse" is still conspicuous in the windows of not a few public-houses in London.

CORONERS, DOCTORS, AND DEATH CERTIFICATES.

A LETTER we publish elsewhere shows how much care should be taken before readily believing a statement discreditable to a medical man, though made before a coroner and a jury. Our own attitude towards the statement—that a medical man offered to give a certificate of death for 3s. 6d.—was one of simple incredulity. We did not believe that a medical man could act as Mr. Ayres was alleged to have acted in this case. The letter throws great light on the difficulty of knowing what to do in some serious cases among the poor. Surely 3s. 6d. for attendance at home for a week on a child very ill was little enough; yet it was declined by the parents, who exercised their minds rather in doubting whether the doctor could do good than in giving him the opportunity of doing it. It was the mother herself who conceived that a medical certificate could be bought without proper medical attendance and without paying even a very moderate sum for it. We may pity those whose ignorance or whose poverty leads them—and there is no evidence here that it was pure poverty—to regard a doctor as an authority for death certification, and not a physician to prevent death. But it is clearly the duty of medical men in such cases to withhold certificates. The carelessness with which death is regarded by the public must not be shared by medical men.

HOSPITAL REGISTRATION.

It will be seen from the report given in another column that the meeting of registrars at King's College Hospital on the 6th inst. resulted in the adoption of a definite resolution, which is likely to lead to good results in the improvement of the registration of disease. The object of the meeting was to take steps to secure greater uniformity in such registration at the hospitals, and the interesting statement of Mr. Howlett showed clearly the varying systems at present in vogue. Many of the gentlemen present gave their experience of hospital registration, and, as might have been expected, opinions differed as to the comparative merits of these systems. It became obvious that it would not be possible to establish a uniform plan at the different hospitals in the matter of recording data, even if this were desirable, but there was an unanimously expressed opinion that the

actual work of registration might be made uniform. As long as the required observations are made it does not much matter for registration purposes whether these are done by the registrar himself, or by his assistants, the important point being that the collection of the data should be pursued on the same lines in every hospital. This it would not be difficult to effect, provided—as the attendance at the meeting of representatives from eight out of the eleven metropolitan hospitals showed—that there is evinced a common desire to make the effort. The first step in this direction was the unanimous adoption of a resolution to form an Association of Hospital Registrars, which is to hold its first meeting at King's College Hospital on Nov. 3rd, when the subject of a revised index of diseases will be taken in hand. We shall watch the further progress of this movement with interest, and shall expect to see it bear early fruit in the statistical tables and reports now issued by nearly all the registrars of our hospitals.

THE NEWCASTLE-ON-TYNE INFIRMARY.

THE *Newcastle Chronicle* of October 8th, in reporting the proceedings of the quarterly court of the governors of the Infirmary of Newcastle-on-Tyne, announces the resignation of Dr. George Y. Heath as senior surgeon. The Mayor, the Sheriff, Dr. Bruce, and others, expressed feelingly their regret and sense of loss in connexion with this step on Dr. Heath's part. Dr. Heath's retirement from a post of prominence is a matter for more than local regret. He has been long regarded as one of the leaders of surgery in this country, and has contributed largely to that elevation of surgery which is so conspicuous in the last decade or two. The authorities of the Infirmary have appointed Dr. Heath consulting surgeon to the Infirmary, and so will retain the advantage of his opinion and advice when necessary. It is due to Dr. Heath that the governors should fill up the appointment with a sole regard to perpetuating the goodly fame of the Newcastle School of Surgery. Already we hear of six candidates in the field—viz., Messrs. Page, Jeaffreson, Williamson, Dodd, Dixon, and Scotland. Mr. Page's long connexion with the Infirmary as senior house surgeon, and lately as senior assistant surgeon, gives him a great advantage in the contest; but should he be elected the governors will have a difficult duty to decide between the claims of the remaining gentlemen, most of whom will probably contend for the post of assistant-surgeon.

THE CORK FEVER HOSPITAL AND DR. MACNAUGHTON JONES.

A SPECIAL general meeting of the subscribers to the Cork Fever Hospital is announced for the 15th instant at the Royal Cork Institution, to receive the report of the General Committee on the management of the hospital; and if approved, to adopt the recommendations contained in the report.

At a meeting of the Council of the Royal College of Surgeons in Ireland, held on the 7th instant, the following resolution was adopted:—"That on the consideration of the published reports of an inquiry recently held in Cork, with reference to certain charges brought against Professor Macnaughton Jones, a Fellow of the Royal College of Surgeons in Ireland, the Council of the College desires to express its opinion that the conduct of Professor Jones, as established by the investigation, was in accord with the accepted practice of medical science, and with professional usage; and that it gave no just grounds for the accusations to which he has been subjected."

At a special meeting of the Council of the Irish Medical Association, held on the 5th instant at the Royal College of Surgeons, Dublin, the following resolution was unanimously adopted:—"That the Council of the Irish Medical Associa-

tion, having regard to the facts disclosed in the recent inquiry respecting occurrences at the Cork Fever Hospital, and being of opinion that Dr. Jones acted conscientiously within the best of his judgment as a physician, and in complete accordance with professional propriety, hereby expresses its sympathy with him in regard to the charges made against him. That this Council, furthermore, in vindication of the freedom of action of a medical attendant responsible for the life and health of his patient, cannot recognise the competency of any non-medical tribunal to pass judgment on a question purely of medical science; nor does this Council consider that any physician should be held responsible for results so long as due skill and care have been devoted by him to the treatment of the patient entrusted to him. That a copy of this resolution be forwarded to Dr. Jones, and to the editors of the weekly medical journals."

Dr. John Adderley, resident medical officer of the hospital, has, we are informed, tendered his resignation.

THE PIROGOW JUBILEE.

ON the 2nd inst. the jubilee of Dr. Nicholas Pirogow's entry into the profession of medicine was celebrated. Fifty years have passed since the celebrated Russian surgeon began his career, and all ranks and classes of the Russian people have been eager to seize the occasion of testifying their affectionate admiration and regard for him. The *Voice*, writing of the event, says M. Pirogow's name is associated with every reform which has been effected in Russia during the half-century in aid of suffering humanity. We have seen him, heedless of self, devoting his care to the wounded on the field of battle during the Franco-German war, and to the sick and wounded in our camps during the recent Turkish war. Russia knows how to appreciate worthily a man who has done so much for her, and the nation will join its voice with the voices of the Medical Council of the Ministry of the Interior, who have addressed M. Pirogow as follows: "We have the agreeable duty of expressing to you, an honorary member of the Council, our most sincere congratulations on the occasion of the fiftieth year jubilee of your scientific activity, and recording our tribute of admiration to your merits. The Medical Council trusts that you will still be spared many years, to the advantage of science and to the honour and glory of our country."

THE ORIGIN OF HOSPITAL SUNDAY.

THERE be many to claim the credit of what is now become one of our best and most established institutions—Hospital Sunday. A very strong case is to be made out for giving the credit to the late Canon Miller when living at Birmingham. We ourselves are vain enough to believe that we have some claim to be considered amongst the earliest and most ardent promoters. But we must allow priority to the good people of Aberdeen. The facts adduced from the books of the Aberdeen Infirmary by the treasurer, show that a collection has been made in Aberdeen on the first day of the year since 1784 for the Infirmary, and that such a collection has been regarded by all denominations as at once a privilege and a duty.

COLLEGE OF PHYSICIANS, IRELAND.

WE understand that there will be a contest for the presidency of the College of Physicians of Ireland, the candidates being Dr. Johnston and Dr. Hayden. The election will take place next Monday, and will be by ballot.

A MEDICAL STUDENTS' SOCIETY has been formed in Melbourne. There are, it is stated, over one hundred and fifty students attending lectures in the medical school of the University of the Australian city.

THE Ophthalmological Society of Great Britain and Ireland will meet during the present year at the rooms of the Medical Society, 11, Chandos-street, Cavendish-square. The first meeting will be on Thursday, 28th inst., at 8.30 P.M., when the rules of the Society will be considered, new members elected, and papers read by Mr. Critcheff, Mr. Hutchinson, Mr. Higgins, and Dr. Hughlings Jackson. Living specimens should be in attendance at 8. Applications for membership and notice of intended communications should be sent to the secretaries, Dr. Stephen Mackenzie, 26, Finsbury-square, E.C.; Mr. Nettleship, 4, Wimpole-street, W.

DR. ALFRED HUDSON, of Dublin, has resigned the Regius Professorship of Physic in the Medical School of the University of Dublin, in consequence of declining health. He was appointed early in 1878 as a successor to the late Dr. William Stokes. There are at present two candidates for the vacancy—viz., Dr. John T. Banks, and Dr. Moore, King's Professor of Practice of Medicine in the University. Should Dr. Moore obtain the post he will resign his present appointment. The emoluments attached to the office amount to £100 per annum. The appointment lies with the Board of Trinity College, who will probably elect a successor to Dr. Hudson in about a month or six weeks.

THERE is now in Barclay ward (Rachel block), under the care of Dr. Sansom, a case of hystero-epilepsy, in which the fits are provoked by pressure over the ovarian regions; they are attended with the attitude of "crucifixion" and all the typical phenomena described by Professor Charcot. The patient suffers from obstructed dysmenorrhœa, which Dr. Herman is treating by dilatation of cervix uteri. There is also a case of hysterical paraplegia; improving under treatment (by Dr. Herman) for uterine retroversion and cervical endometritis; paralytic phenomena receding.

A MEMBER of our profession has, we regret to learn, been a victim of the lawless spirit abroad in Ireland. According to the report of the Dublin correspondent of *The Times*, two ricks of hay and oats, worth £200, the property of Dr. Alexander Patton of Finglas, were burnt down on the night of the 5th inst. The outrage appears to have been committed to avenge some fancied wrong involved in the doctor engaging as servants two men from the north of Ireland.

THE death, on the 7th inst., of Deputy Surgeon-General Thomas Hunter, late of the Army Medical Department, is announced. Dr. Hunter served for many years in the 4th Queen's Own Hussars. His death on Thursday week was very sudden, at the Army and Navy Club, St. James's-square, he was found by one of the waiters in the committee-room, apparently asleep, but on assistance being sent for it was discovered that life was extinct. Dr. Hunter was unmarried.

AT St. Bartholomew's Hospital, in Sitwell ward, under the care of Mr. Willett, there is a child with congenital deformity of the left scapular arch; a bridge of bone unites the scapula to the spinous process of the sixth cervical vertebra. As the mobility of the arm is much impeded, it is proposed to remove the intervening bridge of bone.

AT the Medical Society of London on Monday evening next Dr. Hughlings Jackson will read a paper on "Cases of Recovery from Symptoms of Organic Brain Disease."

THERE seems a probability of Professor Bain becoming a candidate for the office of Assessor to the Council of the University Court of Aberdeen.

In a case of aortic stenosis, with slight murmur of mitral regurgitation and post-diastolic murmur heard near the apex, now under Dr. Sansom's care in the London Hospital, an interesting question of diagnosis arose between "slight" aortic regurgitation and mitral stenosis. It is concluded that the murmur heard at the apex is aortic regurgitant.

THE election of Council of the Surgical Society of Ireland for the session 1880-81 will take place on Monday, November 1st, at the Royal College of Surgeons. Those entitled to vote must, besides being Members of the Society, also be either Fellows of the College of Surgeons or of the College of Physicians in Ireland.

ACCORDING to the report of the University of Dorpat for the year 1879, the number of students studying medicine there during the year was 475.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

St. Matthew, Bethnal-green (area, 755 acres; inhabited houses, 17,475; estimated population, 133,400).—Dr. Bate introduces his report for 1879 by an amusing extravagance which forcibly indicates the great changes going on in this part of the metropolis. He says if the alterations being made by the Great Eastern Railway Company, the School Board for London, and the Metropolitan Board of Works, particularly those involving the demolition of small house property, are continued much longer, Bethnal-green will become a huge agglomeration of board schools, intersected by railways and new streets. Certain it is that great clearances of old and dilapidated cottage property have been effected, and are still being carried out in the district, and the numerous large, well-built board schools form a most conspicuous feature in it; but hardly more conspicuous than the great blocks of Improved Labourers' Dwellings which have sprung up and are still springing up there, and which it is obvious will presently overshadow even the board schools. Indeed, as Dr. Bate himself shows, his prospective description of Bethnal-green would have been more accurate if he had said, "a huge agglomeration of Board Schools and Improved Dwellings," &c. The arrangement of these blocks of improved dwellings is said to be very good, the ventilation being excellent, and the drains well constructed. Bethnal-green, of which the name is associated with so much that is painful in the sanitary history of the metropolis, has obviously, according to Dr. Bate, a much happier sanitary future before it; and it is pleasant to find how eagerly that gentleman is striving, by precept and example, to help onward the tide of improvement which has now fully set in.

The birth-rate of Bethnal-green in 1879 was 39.3 per 1000 of the inhabitants (as against 36.5 for the whole of the metropolis), and the death-rate was 23.0 per 1000 (as against 23.3 for the whole metropolis). The death-rate has been stationary during the last three years, and on this Dr. Bate observes:—

"I cannot say that I am content with this stationary condition of things. We are only holding our ground, while we ought to be diminishing our mortality. Certainly it is in each year a little less than the general metropolitan rate, but I should like Bethnal-green to be something more than an average London parish. We have a gravelly soil, wide, well-paved roads, good sewers, a fine public park, and few offensive trades carried on in our midst; still the insalubrious condition of many of our houses (and not always the smallest ones) remains a patent fact, and undoubtedly keeps up the death-rate. The drainage arrangements of many houses are as bad as they can well be, leaky and unventilated. What we are endeavouring to abolish as much as possible just now are sinks in washhouses communicating with foul drains,

and inside closets badly placed, or not thoroughly ventilated. These we get altered as soon as we discover them, but sanitary officers are not ubiquitous, and unless cases of bad drainage and defective sanitary arrangements are reported to us in time, they are frequently not discovered till the mischief is done, and a death from fever in the Registrars' weekly returns draws our attention to the locality. If people would only learn the A B C of sanitary science, keep out drain air and open their windows so as to let in fresh air, we should have fewer deaths and a healthier population.

"It cannot be too strongly impressed upon the owners of house property that it is not sufficient merely to trap a drain; if that drain have an opening inside the house it should be ventilated by a pipe continuous with some portion of it carried right above the eaves, and left wide open. If a proper trap with an air inlet be placed between the house-drain and the sewer so much the better, but sewer air is not so bad as it is represented, and is always infinitely better than that of small pipe drains. The sewer is well ventilated, frequently flushed, and fairly clean, so that we cannot do better than strive to obtain a similar condition of things in our small pipe drains, which, from the vile manner in which they are frequently laid and arranged, are often little better than tubular cesspools pouring their fetid effluvium into our dwellings."

We get an instructive illustration from the report of the value of infectious disease hospitals. Forty-five cases of small-pox were reported to the Sanitary Authority, and of these not less than thirty-four were removed to hospital. It cannot be doubted that if a like proportion of other dangerous infectious diseases had been isolated in hospital, a marked diminution in their prevalence must have happened. The people generally have not, however, yet reached a pitch of sanitary cultivation fully to apprehend this, but growth is slowly taking place in this direction, and sooner or later will bear fruit.

Commenting on the readiness with which the child's brain takes on morbid action, Dr. Bate observes:—"The liability of an organ like a child's brain, rapidly growing and developing as it is, to take on inflammation and disease is well known, and must be taken into account when considering any plan for the education of children. My own opinion is that no young child should be forced to learn; and that to take tender little youngsters and herd them together in stuffy or draughty schoolrooms for purposes of so-called education, is fraught with danger, not only to their brains, but to their bodies too, for no better plan of spreading infantile contagious disorders could well be devised." Taking this in conjunction with the previous gibe on Board Schools, we fear it is to be concluded that Dr. Bate does not affect these institutions.

In an appendix Dr. Bate describes and gives a plan and elevation of the new mortuary erected at Bethnal-green. The mortuary contains separate rooms for the dead from infectious and non-infectious diseases, and a post-mortem room with necessary conveniences.

REPORT OF THE LOCAL GOVERNMENT BOARD.

The ninth Annual Report of the Local Government Board (1879-80) has issued from the Parliamentary Press. It forms, as is customary with these reports, a portly volume and refers to the last year of the Rt. Hon. G. Selater-Booth's administration. The report is pretty equally divided between the Poor-law and Public-Health work of the Board, while a bulky appendix contains much tabular matter and numerous instructional memoranda and circulars published by the Board during the period to which the report refers. The Public-Health division contains very many things of great interest, a detailed examination of which we reserve for the moment. On the whole, the general impression left by the Report is that the Board in Public-Health matters is shaking itself better into shape—feebly and sluggishly of a certainty, but still tending in a more rational direction. The Board has not the courage frankly to avow (we give it the credit of having the wisdom to perceive) that the difficulties it has had and still has to contend with, are chiefly of its own creation, and so it stands at a disadvantage in its endeavours (such as they are) to get its public-health administrative policy into a right track. Moreover, feeling the force of the apophthegm that boards have neither heads to think, nor hearts to feel, let us be thankful for such indications of amendment as we think we trace in the 672 pages octavo of printed matter now before us.

A VENTNOR OR MALEBOLGE?

Fulham is having constructed within its area a great blessing or a great curse. That is to say, according to local views; for it may chance that the construction is neither the one nor the other, but simply what it professes to be—to wit, a common-place commercial operation. An enterprising dairyman there, in fact, is building a cowshed to contain 100 cows. Now there is nothing necessarily unwholesome about cow-keeping or that should tend to unwholesomeness where the keeping is carried out in the midst of a community of which the sanitary authority does its administrative duties in a reasonably systematic manner. But cow-keepers and sanitary administrators have, unfortunately, the weaknesses of ordinary men, and certain persons living near to the spot where this cowshed is being built, distrusting equally the one and the other, complain that the shed must prove a monstrous nuisance, and, further (but in what manner does not appear), a means of spreading "fever and other diseases" in the neighbourhood—a matter held to be of no little consequence, seeing that schools are being erected by the London School Board, for 1000 children, hard by. On the other hand, it is averred that the cowshed, so far from being a nuisance, will prove an inestimable advantage to the neighbourhood. Is it not well known that the atmosphere of cowsheds is excellent for persons suffering from incipient consumption? Have not physicians in many places, and for many years, been in the habit of sending their consumptive patients to live in lofts above cowsheds, holding that breathing the moist, odoriferous air of the sheds, especially when occupied by the cows, is highly beneficial to their patients? And as to dirty cowsheds, is not the dirt an important element in the beneficial influence of the atmosphere? As a member of the Vestry ingeniously put it when this case was before that body, "the cowshed, so far from being a nuisance, would, if properly managed, become a health-resort." However, the local authority sympathise with the complainants. The building of the cowshed cannot be stopped, nor can the question of nuisance seemingly arise until cows are in it; but the Vestry propose to oppose the granting of a licence for the use of the shed as contemplated.

LONDON "DUSTING."

Every now and then a faint hope arises of some London sanitary authority becoming aroused to the error of its ways as to "dusting," and setting a good example to its brother authorities within the metropolitan area. Some such hope sprang up when, at a recent meeting of the Hackney vestry, Mr. Fitch moved "That, in the opinion of the Vestry, it be now taken into consideration whether it is not absolutely requisite, as a sanitary measure, to avoid the continuance of those centres of infection known as dust-bins; and that the dust and waste of householders should be removed daily, as it is in well-regulated municipalities—such resolution to come in force at the expiration of this present dust contract." But £20,000 a year was held to be too great a sum to pay for the privilege of being included among well-regulated municipalities and the greater wholesomeness of the district, and the motion was withdrawn. Metropolitan ratepayers complain loudly and bitterly of the evils inflicted upon them by imperfect dusting, and so long as they confine themselves to mere complaining without organising measures for controlling the action of their representatives on the Vestries and District Boards of Works, it is unlikely that we shall witness those bodies eager to carry out a reform which presents little to enlist the imagination of ambitious representatives. "Dusting" is a work of repulsive detail, of which the results mainly affect the individual householder. It has not the merits even of street scavenging, which are obvious to all men, and serve the part of whitewashing, so to speak, the metropolitan sepulchre.

WATERED MILK.

A Berkshire farmer pleaded "guilty" at the Marylebone police-court a few days ago of having sold milk diluted with water, but he explained that the water had accidentally got into the milk while the latter was being cooled in a brook. This mode of cooling demands the notice of medical officers of health, for we remember having our attention directed not long ago by a farmer, residing in the same county, to an ingenious arrangement he had made, as he thought, for cooling his milk. He had dammed a brook running through his farm so as to form a pool of sufficient depth to immerse

a milk-churn. To a tree above this pool he had fixed pulleys with ropes, for readily placing the churn in and raising it from the pool. At the time we were there a full churn was suspended in the pool, with its brim just above the surface of the water. The arrangement appeared to be irreproachable, and did not want an element of the picturesque. The brook ran clear and sparkling beneath banks thickly covered with wood; the pool, also bright and clear, was surrounded by trees, and the murmur of the water above and below filled the air with a pleasant sound. But curiosity prompting us to follow up the course of the brook a few yards, there we found, hidden among the foliage, and placed across the stream, the one privy of a populous farmstead! The brook, while it served for cooling the milk, served also for carrying away all that was most revolting of human filth from a numerous household.

A SANITARY MYTH.

Certain questions relating to defective structural arrangements in new buildings, and especially to defective foundations, coming before the Hampstead Vestry on the 30th ult., the chairman observed that they were matters for the consideration of the district surveyor. Whereupon a member remarked that the district surveyor was "a myth." It must be admitted that there is very much to be observed in the new buildings springing up within the metropolitan area, particularly towards the margin, which tends to confirm the conclusion, that in regard to numerous important points of construction of new buildings the district surveyor is, in fact, a myth. How this comes about it is no part of our present purpose to consider, but it would be a clear gain if the public were enabled to discriminate between presumed functions of the surveyor that are mythical and functions that are real.

Both the Holborn guardians and the Marylebone guardians have applied to the Metropolitan Asylums Board for permission to rent the Hampstead Hospital pending the appeal in "Hill v. the Asylums Board," in order to relieve the pressure which now exists upon their workhouse accommodation. They would transfer to Hampstead such occupants of their workhouses as might be fittingly accommodated there. The Asylums Board assented to the application, subject to the approval of the Local Government Board.

The Marylebone Vestry have passed a resolution expressing the deepest regret at the death of Dr. Whitmore, and conveying to the family of that gentleman their sincere condolence with them in their bereavement. The resolution also recognises the great energy, ability, and uniform urbanity with which Dr. Whitmore carried out his duties as medical officer of health. The Vestry further directed that a copy of the resolution, framed and glazed, should be forwarded to the widow and family.

A very fatal outbreak of scarlet fever is reported at Loughton, near Epping. The Local Government Board has sent a medical inspector to the spot to confer with the sanitary authority on the measures to be adopted for arresting the spread of the disease. The schools of the locality have been closed, one of them converted into a hospital, and trained nurses secured to attend upon the sick.

The Halsted Board of Guardians, sitting as Rural Sanitary Authority, at their meeting on the 17th ult. appointed a committee to consider the provision for the Union of hospital accommodation for cases of infectious sickness. It was suggested that two or three cottage hospitals would best meet the requirements of the district.

A curious incident is reported from Olton, near Solihull, in the vicinity of Birmingham. The sanitary authority, on seeking for the source of a nuisance, discovered that a drain on a gentleman's property had been wilfully and carefully blocked with clay, turf, bags, and wood.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The marked decline in English mortality which occurred in the previous week was scarcely maintained last week. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 4633 births and 3118 deaths were

registered last week. The births were 552, and the deaths 157 below the average weekly numbers during 1879. The deaths, however, showed an increase of 58 upon those returned in the previous week, and were equal to an annual rate of 21·7 per 1000, whereas in the six preceding weeks the rate had steadily declined from 25·1 to 21·3. The lowest death-rates in the twenty towns last week were 14·6 in Plymouth, 15·6 in Brighton, 16·9 in Sheffield, 17·2 in Birmingham, and 18·1 in Oldham. The rates in the other towns ranged upwards to 30·6 in Liverpool, 31·2 in Salford, 34·4 in Sunderland, and 35·3 in Leicester. The high rates in the four last-mentioned towns were mainly due to excessive zymotic fatality. During the thirteen weeks ending on 2nd inst., the death-rate in these towns averaged 23·2 per 1000, against 23·8 and 18·3 in the corresponding periods of 1878 and 1879.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 1009, 912, and 657 in the three preceding weeks, further declined last week to 617; of these, 281 resulted from diarrhoea, 141 from scarlet fever, 68 from fever (principally enteric), and 60 from whooping-cough. The annual death-rate from these seven diseases averaged 4·3 per 1000 in the twenty towns, and ranged from 2·7 and 2·9 in Brighton and London, to 10·4 and 14·3 in Salford and Sunderland. The death-rate from diarrhoea did not exceed 1·4 per 1000 in London, but ranged upwards in the nineteen provincial towns to 4·8 in Leicester, 5·3 in Salford, and 5·4 in Sunderland. Scarlet fever caused more deaths than in any recent week, and showed the largest proportional fatality in Sunderland, Brighton, and Salford. Measles was somewhat prevalent in Leicester. The death-rate from enteric fever was excessive in Salford, Plymouth, and Leeds; and small-pox caused five more deaths in London. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 116, 105, and 95 at the end of the three preceding weeks, further declined to 92 on Saturday last; fourteen new cases were admitted to these hospitals during the week, against 6 and 24 in the two previous weeks. The Highgate Small-pox Hospital contained 7 patients on Saturday last.

The deaths referred to diseases of the respiratory organs in London, which had steadily increased from 124 to 199 in the four preceding weeks, further rose last week to 266, and exceeded the corrected weekly average by 42; 149 resulted from bronchitis, and 69 from pneumonia. The annual death-rate from lung diseases was equal to 3·8 per 1000 in London, 5·9 in Liverpool, and 5·6 in Salford.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 19·6 per 1000, against 18·9 and 18·8 in the two preceding weeks; this rate was, however, 2·1 per 1000 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 16·8 and 17·4 in Leith and Dundee, to 20·8 and 22·3 in Edinburgh and Paisley. The fatal cases of the seven principal zymotic diseases in the eight towns, which had been 153 and 134 in the two preceding weeks, further declined to 116 last week; they included 46 from diarrhoea, 30 from scarlet fever, 13 from diphtheria, 13 from whooping-cough, 3 from measles, and not one from small-pox. The annual death-rate from these seven diseases averaged 4·7 per 1000 in the eight towns, and slightly exceeded the rate from the same diseases in the twenty English towns. No death from any of the seven diseases was recorded in Perth, while the zymotic death-rate in the other towns ranged from 1·8 in Leith to 4·6 and 7·9 in Glasgow and Edinburgh. The fatal cases of diarrhoea in the eight towns, which had been 69, 53, and 51 in the three previous weeks, further declined to 46 last week, and were equal to an annual rate of 1·9 per 1000, corresponding with the average rate from the same disease in the twenty English towns. Edinburgh showed the largest proportional fatality from diarrhoea among the Scotch towns last week. The fatal cases of scarlet fever further declined to 30 last week, from 45 and 33 in the two previous weeks; 15 occurred in Edinburgh and Leith, and 12 in Glasgow. The 13 deaths referred to diphtheria included 7 in Glasgow, 2 in Edinburgh, and 2 in Greenock. The 11 fatal cases of fever showed a decline of 6 from the number returned in the previous week; 4 were returned in Glasgow, 3 in Aberdeen, 2 in Edinburgh, and 2 in Dundee. The deaths attributed

to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) were 66 in the eight towns last week, against 68 and 76 in the two preceding weeks; the annual death-rate from these diseases last week was equal to 2·7 per 1000 in the eight towns, against 3·2 in London.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, although again excessive, showed a further slight decline from that which prevailed in the three preceding weeks. The annual death-rate in the city in the four past weeks has steadily declined from 39·3 to 33·3 per 1000. During the thirteen weeks which ended on the 2nd inst. the death-rate in the city averaged no less than 34·6 per 1000, against 21·3 in London, and 21·8 in Edinburgh. The 201 deaths in Dublin last week included 53, or more than 26 per cent., which were referred to the seven principal zymotic diseases, showing, however, a further decline of 10 from the high numbers returned in the three previous weeks; 22 resulted from diarrhoea, 11 from whooping-cough, 7 from fever, 7 from scarlet fever, 5 from measles, 1 from small-pox, and not one from diphtheria. The annual death-rate from these diseases was equal to 8·8 per 1000 in Dublin, whereas it did not exceed 2·9 in London, and 7·9 in Edinburgh. The fatal cases of diarrhoea in Dublin, which had been 44 and 33 in the two previous weeks, further declined to 22 last week, and were equal to an annual rate of 3·6 per 1000; the annual death-rate from diarrhoea in London did not exceed 0·9 per 1000. The 7 deaths referred to fever, including typhus and enteric or typhoid, showed a decline of 3 from the number returned in the previous week. The deaths from scarlet fever also showed a decline; whereas those from whooping-cough and measles were somewhat more numerous. The rate of infant mortality in Dublin showed a further decline from that which had prevailed in recent weeks.

SUMMER DIARRHOEA IN LEICESTER.

It is many years since the exceptional fatality of summer diarrhoea in Leicester began to attract the attention of sanitarians, professed and amateur, and yet during the summer just over the death-rate from this disease in the town has been higher than that recorded in any of the nine preceding years. The deaths returned from diarrhoea in Leicester, which in the nine years 1871 to 1879 had ranged from 265 in 1873 to 60 in 1879, were no less than 343 in the thirteen weeks ending last Saturday, and were equal to an annual rate of 10·6 per 1000. The fatal cases of diarrhoea, which were but 2, 5, and 9 in the first three weeks of July, afterwards rose rapidly to 50 in the second week of August, after which the numbers declined slowly, and were 22 and 24 respectively in the last two weeks under notice. The fatality of other zymotic diseases was not excessive in Leicester last quarter; 43 deaths were referred to measles, 16 to scarlet fever, 13 to fever (probably enteric), 11 to diphtheria, 5 to whooping-cough, and not one to small-pox. In English urban populations more than 80 per cent. of the deaths referred to diarrhoea during the summer are usually of infants under one year of age, and it is not therefore surprising to find that infant mortality was exceptionally high in Leicester last quarter. During the thirteen weeks under notice 456 deaths of infants under one year of age were registered within the borough, against 207 and 179 in the two preceding quarters of the year; these deaths were equal to 346 per 1000 births registered. The proportion of infant mortality measured in this manner averaged 238 per 1000 in the twenty towns last quarter; it was equal to 212 in London, whereas it averaged 263 in the nineteen large provincial towns. With regard to the annual death-rate from diarrhoea last quarter, we have seen that it was equal to 10·6 per 1000 in Leicester; it averaged 4·4 in the twenty large towns (against 2·3, 4·2, and 1·2 in the three preceding corresponding quarters), and while it did not exceed 3·3 in London, it averaged 5·6 in the nineteen large provincial towns. The question naturally recurs, Why was the death-rate from diarrhoea in Leicester last quarter nearly twice as heavy as the average rate from the same disease in the nineteen provincial towns, and more than three times as great as the rate that prevailed in London during the same period? The average weekly number of deaths from diarrhoea in Leicester did not exceed 6 in July, while it increased to 35 in August, and was 36 during the five weeks ending October 2nd. It is worthy of note that nearly 99 per cent. of the causes of deaths regis-

tered in Leicester last quarter were either certified by registered medical practitioners or were the subject of inquests. It is strange, indeed, if under those circumstances some light cannot be thrown upon this annual sacrifice of infant life in Leicester. Two facts bearing upon this subject may be taken as already proved—namely, that infant mortality in Leicester is remarkably excessive from other causes as well as diarrhoea, and that Leicester is not a generally unhealthy town, inasmuch as the rate of mortality prevailing among its population above infancy bears very favourable comparison with that in most of the other large English towns. It should not surely be impossible to discover why infant mortality in Leicester is so high, while the death-rate at all other ages is comparatively low.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

DR. BEDDOE'S ADDRESS.

Dr. Beddoe's address as President of the Health Department of the Social Science Congress held in Edinburgh covered a wide range, and presented much matter for thought. In especial he impressed upon his hearers somewhat more enlarged views of the influences and agencies which have concurred in lowering the death-rates of certain sections of our population than have lately obtained to any considerable extent among sanitary workers, and he showed the erroneously limited fashion in which the term "preventable" was generally made use of as applied to disease. Taking the position that man is seen at the healthiest (physically) when he is most scattered and bears the least proportion to surrounding nature, he dwelt upon the steadily increasing tendency in civilised countries to the aggregation of people in towns, and the numerous complex questions touching the physical future of our communities arising therefrom. This "urbanisation" of man (to coin a convenient phrase for the moment) tends, Dr. Beddoe thinks, to a slowly progressive physical deterioration, but one, perhaps, not beyond the reach of arrest, if the problem be rightly apprehended. There is excellent promise of this in the appreciable effects of the great moral and social changes which have occurred during the century—the protection afforded to young children in mines and manufactures, the spread of education, and the generally more comfortable state of life of the masses—changes which have exercised a clearly measurable influence upon the well-being of the people. We are only now beginning to see our way with clearness to definite methods of dealing with the deteriorating influences peculiar to towns. We are here confronted with difficult questions of organising for the best our sanitary administration, ordering for the better our habitations, and securing reasonable purity of water-supply. We have, moreover, to reconcile our objection to the multiplying of laws (with the accompanying evil of multiplying opportunities for jobbery) with the obvious insufficiency of existing laws. Clearly, however, the liberty of builders and plumbers to perpetrate unrestricted mischief in our dwellings must be restrained, whatever our theoretical objections may be to increasing and harsher legislation on sanitary subjects. But legislation to be effective cannot pass beyond the knowledge of the persons legislated for, and our soundest improvements in sanitary and other matters affecting the physical welfare of the people will be those which keep pace with their growing knowledge. Hence, underlying all true progress in the health-reform of the kingdom, must be the sound sanitary education of the masses.

THE SOCIAL SCIENCE CONGRESS.

The Health Department of the Social Science Congress has been busily engaged in Edinburgh under the presidency of Dr. John Beddoe, F.R.S. The question of "What are the best areas for sanitary purposes, and how far should there be a revision of the mode of electing and continuing the services of the officers under the Public-Health Acts?" has been discussed, and papers on various matters concerning the public health read by Mr. Sherif Spens, Dr. Hardesty (Galashiels), Mr. Kenneth McLeod, Baillie Colston, Sir John Rose Cormack, M.D., Dr. Littlejohn, Mr. Johnston, and others.

MR. SYMONS ON HEALTH-RESORTS.

Mr. Symons, professedly seeking information on our health-resorts at the Congress of the Sanitary Institute, Exeter, contrived to raise a vision of horror which would daunt any but the most ardent enthusiast in such a subject. Discoursing on some deficiencies in our knowledge respecting health-resorts, he showed that these were so numerous and so big that it would require, at a reasonable guess, about a generation of physicians, water-analysts, geologists, meteorologists, sanitary engineers, and statisticians to lay a foundation for making them good. It is some relief to find that the mixed physician and sanitary worker, the "sanitarian" properly so-called, as it is the habit now to designate him, is not mentioned, and that he may go on his way rejoicing; in other words, enjoying health-resorts from a lower plane of observation than Mr. Symons would recognise. He has a scheme for forming a public body, "perhaps a committee comprising representatives of the leading medical, sanitary, and scientific societies," to undertake the task of preparing an exhaustive account of our watering-places, medical, water-analytical, geological, meteorological, and so forth, and for giving the results to the world. It is a scheme which may be commended to the Institute as having abundant room for the exercise of its multifarious functions for an indefinite period of time to come, and which when (if ever) completed will at least form an important help to filling up our library shelves. We sympathise with Mr. Symons's aspirations in the matter, are prepared to be grateful for all the information he can get for us or give us on the subject, but we doubt his having seized upon it quite accurately. The number of places in this country regarded as health-resorts in the sense of being resorts for invalids in search of health are not very numerous, and fall far below those health-resorts which are frequented by persons seeking rest or recreation—most commonly recreation. In the one case we have to deal with a medical question; in the other with a question of individual tastes as various as the different modes in which rest and enjoyment are sought. In the first-named case, the health-resort proper, so to speak, information of the sort Mr. Symons seeks is desired in the interest of the invalid and of medical practice; in the second-named case, the requirements of the visitor are met by a reasonable assurance that the local sanitary arrangements are such as every authority is empowered to make. True, the "health-resorts" of the two classes may unite in one and the same place, but the distinctions noted between them are sufficiently obvious to make discrimination easy. A work of the kind suggested by Mr. Symons limited to the "health-resorts" proper would be a welcome addition to our literature; but extended indiscriminately to all places which have or may aspire to the name would, we venture to think, be a huge error and useless labour. Let us hope Mr. Symons will somewhat moderate his views in this direction.

SEWER VENTILATION AND SANITARY PROTECTION.

The recent correspondence in *The Times* on sewer ventilation chiefly brought to light the astonishing ignorance which exists among some of the more highly educated classes of society of certain of the most rudimentary sanitary matters. It was obvious that the majority of the writers had not given a moment's care to ascertain if anything definite was known on the subject on which they so unhesitatingly wrote and advised, and that they had not the remotest conception of the functions of sanitary authorities in the matter. In fact, the difficulties and dangers which troubled them were for the most part imaginary. If, however, the correspondence should give an impulse to the formation of "Sanitary Protection Associations," good will result from it. An incidental bit of information, contributed during the correspondence by "A Physician," writing from Edinburgh, deserves to be had in memory when sanitary reform comes to the front again in England. He tells us that the northern capital has an officer of which the like does not exist in English towns. He is called the burgh engineer, but his duties appear to differ in several important respects from those of the engineers and surveyors of our local authorities. He is "paid by the rates," says the writer, "and his services are at the call of every ratepayer as occasion arises. Any person suspecting that something is wrong with his drains may send up to the burgh engineer's office, and is always sure of courteous attention. Within a day or two of such application a competent person is sent

down to inspect the premises, and, if necessary, the pavement is taken up and a thorough investigation made. If nothing is found to be wrong, the householder has official assurance to that effect; and if, on the other hand, there are real grounds of complaint, the matter is taken up by the burgh engineer, who notifies the landlord that such and such alterations must be made; and if these are not quickly carried out the work is done by the burgh engineer's men at the landlord's expense. For all this no fee whatever is charged, and of every such case a record is kept at the office, so that on any future occasion it is easy to ascertain exactly what has been done. A general oversight is also given to all new buildings, and I believe that none can now be erected unless the drainage and water arrangements are satisfactory to this most beneficent despot. Why such an officer is not appointed in every town in the kingdom is to me a mystery, and I hope that the good example of Edinburgh will speedily be widely followed in this respect." We hope so too.

DIPHTHERIA IN RUSSIA.

From 1877 to 1880 diphtheria has been very fatally prevalent in the district of Tchiguirine, government of Kiew, the number of the sick from the disease sometimes having reached (as reported) no less than 6000. Under these circumstances, the medical assistance usually provided for a district—namely, one physician with six assistants—proved lamentably insufficient, and M. Soukatchew, the physician for the district in question, devised a mode of relieving this difficulty. He proposed to form a staff of women willing to give their help for the purpose, to instruct them in the general mode of treating a case of diphtheria, to furnish them with medicaments, and distribute them in the villages where the disease appeared and where proper medical care could not be had. He proposed, in fact, to train at the moment a corps of medical nurses, who would serve after a fashion as substitutes for medical men, where these could not be obtained. This proposition was submitted to the local authorities, and it was willingly acted upon. M. Soukatchew himself undertook the training of the women who volunteered, and expressed himself highly satisfied with the aptitude of his pupils. They were instructed to observe the signs of the malady, to use certain modes of treatment, to separate the sick from the healthy, to disinfect houses (burning infected articles of clothing), and to keep the physician informed of the occurrence of new cases. The plan fell in so well with the notions of the inhabitants of the district that, when at a later period certain sanitary detachments consisting of trained sisters of charity reached the district, they manifested a marked preference for the extemporised sisters.

SPLENIC FEVER.

A curious conflict of opinion is reported from Birkenhead between the officers of the sanitary authority and the officers under the Contagious Diseases (Animals) Act as to the unwholesomeness or not of a carcase, and as to the cause of death of the animal. The slaughter-house inspector, supported by the medical officer of health and a veterinary surgeon, expressed the opinion that the animal (an American bullock) had died of splenic fever; the inspector under the Contagious Diseases (Animals) Acts, the chief meat inspector at Liverpool, two veterinary surgeons, another inspector, and two old butchers, averred that the meat was good, and that the animal had not suffered from splenic fever. The stipendiary magistrate, who had been asked to condemn the carcase, gave the owner the benefit of the doubt, and refused to do so.

The *Globe* of Wednesday states: "The coroner's inquiry into the causes of the typhoid fever epidemic at Rochdale was resumed yesterday. Eleven deaths from fever, and fifty-two cases of infection, are reported to have occurred in the borough during the past two months, and in a considerable number of these cases it was shown that the milk taken by the deceased had been supplied from a particular farm. The jury were of opinion that the evidence adduced was not sufficient to prove from what particular cause the fever arose, but they considered it to have arisen either from infected milk or defective sewers."

At the suggestion of the medical officers of health of the Wandsworth and Clapham District, the Board of Works have resolved to send a memorial to Sir W. Harcourt, urging

that in all cases of uncertified death, where no inquest is held, an investigation should be made, and a certificate of the cause of death given, by the medical officer of health of the district before burial. The Board also resolved to forward a copy of the memorial to each of the vestries and district boards of the metropolis, with a request for their support in the matter.

According to a statement on unhealthy lodging-houses, recently presented to the French Academy of Medicine by M. Marjolin, there are more than 2000 lodgings in the outlying quarters of Paris which derive their light from corridors only, while 3000 have no chimneys. Families of five, six, or ten persons have been found living in one room a few metres square, a single small bed sometimes serving for as many as four or five children.

REPORT OF THE FRENCH MEDICAL COMMISSION ON PLAGUE IN ASTRAKHAN,

1878-79.¹

THE long-expected report of the Commission—or rather Commissioner—despatched by the French Government, early last year, to make inquiry into the outbreak of plague on the banks of the Volga in the government of Astrakhan, has at length come to hand. It is not easy to understand why the publication of the report should have been so long delayed; but such disappointment as may have been experienced from the lateness of appearance is amply repaid by the greater elaboration which it has been practicable to give to the report in consequence of the delay.

The Commissioner appointed was Dr. C. Zuber, surgeon-major, joint professor of Epidemiology in the School of Val-de-Grâce. He left France for the scene of the outbreak of plague in Astrakhan on the 22nd February, 1879, and, in common with the other foreign medical commissioners (as also the Russian), got there when the outbreak was over. He nevertheless employed his time so well during his stay in the lately infected district that he has been enabled to pen a report which, for comprehensiveness and lucidity, certainly carries away the palm from the other reports of the outbreak which have hitherto appeared. We propose here briefly to glance at the general results of Dr. Zuber's inquiry, reserving until another occasion observations on disputed questions arising out of it. We have still hope that the Russian Government will eventually publish the materials they have in their possession relating to the outbreak. That Government, it is understood, contemplated a detailed medical inspection of the delta of the Volga and parts of the littoral of the Caspian, with a view to the discovery of any prevalence of larval or other forms of plague, and it may be that the publication of the official report of the outbreak on the Volga is postponed until the results of this more general inspection can be given.

With regard to the locality of the outbreak on the Volga, the distribution of the disease on both banks of the river, the period of its occurrence, its duration and probable fatality, Dr. Zuber is in accord with previous reporters. He concurs also with them in regarding the disease as true bubonic plague, and he repudiates the notion that it was the black or Indian plague. He lays especial stress upon the tendency of the disease to prevail as a series of house epidemics, killing the majority of the inhabitants of the houses attacked, the mortality ranging from 80 to 95 per cent. Differing in this respect from the British medical commissioners, he regards the spread of the disease by contagion as the most characteristic phenomenon of its diffusion. On the question of origin of the outbreak, moreover, he comes to conclusions widely diverse from those of both the British and the German Commissioners. He thinks it impossible to admit the autochthonous origin of the disease, advocated by Colvill, but spoken of more guardedly by Payne, and he thinks that theory of importation from Mesopotamia by way of the seat of war in Asia Minor, through the intermedium of infected spoils carried to the banks of the Volga by re-

¹ Une Mission Médicale en Russie. La Peste du Gouvernement d'Astrakhan en 1878-79. Rapport présenté à M. le Ministre de l'Agriculture et du Commerce. Par le Dr. C. Zuber, Médecin-Major, Professeur Agrégé d'Epidémiologie, à l'Ecole du Val-de-Grâce, Baillière et Fils.

turning Cossacks (as thought possible by Hirsch), inconsistent with the ascertained facts, and in the highest degree improbable. On the other hand, he regards the hypothesis of an importation from Persia as supported by well-established facts, natural and demonstrable. The frequency of the communications between Astrakhan and Persia, the maritime nature of these relations, the relatively small distance between the two countries, and the insufficiency of their quarantine establishments, all tend, he thinks, to support this hypothesis. Moreover, the presence of "abortive plague" in Astrakhan, and its probable continuance there until 1879, furnish, he believes, confirmatory evidence that the plague on the Volga was derived by importation from the plague previously prevailing in the southern littoral of the Caspian in Persia.

The last word is not yet said on this outbreak of plague on the Volga, and even as we write we have before us certain new contributions of Dr. Tholozan to the literature of plague, which will render necessary a reconsideration of some of the positions taken by Dr. Zuber.

THE SERVICES.

VOLUNTEER AMBULANCE DEPARTMENT.—INSPECTION OF THE 7TH SURREY AMBULANCE CLASS.

The class of volunteers belonging to the 7th Surrey Rifles, who have lately undergone a course of instruction in ambulance and stretcher drill by Surgeon Cyril Lloyd Jones, the regimental surgeon, was inspected on Saturday last at their head-quarters, Kennington-lane, by Surgeon-General A. Shelton, head of the Medical Branch, War Office. The class went through the different evolutions of stretcher drill, and was examined in surgical assistance and the application of dressings, bandages, splints, &c., all of which were skillfully and expeditiously performed. Surgeon-General Shelton congratulated the class most warily on their efficiency, which manifested great care and labour on the part of the instructor, the zeal and regularity which the members had shown in their attendance in the class-room, and their aptitude for the work. Major Bowen, who with the Adjutant, Lieutenant Maclure, of the London Scottish, the Hon. Secretary, and other officers received the Surgeon-General, proposed a vote of thanks, which was most cordially given, to the Surgeon-General for his kindness in making the inspection.

We are requested to announce that the next class of instruction in volunteer ambulance and stretcher drill will commence on Wednesday, October the 13th, at the Guildhall, at 7.30 P.M., and will continue each Wednesday till the end of the year. Application should be made to Lieutenant A. Maclure, London Scottish.

To be Surgeon-General—Deputy Surgeon-General Frederick Freeman Allen, C.B., of the Bengal Army.

ADMIRALTY.—Staff Surgeon Patrick Keelan has been promoted to the rank of Fleet Surgeon to Her Majesty's Fleet, with seniority of 2nd inst. Surgeons William Deacon Isaac and Christopher Harvey have been promoted to the rank of Staff Surgeon in Her Majesty's Fleet. The following appointments have been made:—Surgeon Christopher Pearson, M.D., to the *Crocodile*; Surgeon Robert Redford to Haslar Hospital; Surgeon John Arthur Langdon, additional, to the *Duke of Wellington*.

HOSPITAL REGISTRATION.

A MEETING for the purpose of considering the question of uniformity of registration in the metropolitan hospitals was held at the King's College Hospital, on Wednesday, Oct. 6th; Dr. Sidney Coupland in the chair.

After a few introductory remarks, the chairman called on Mr. Howlett to open the discussion.

Mr. HOWLETT first proceeded to explain the causes which had led to the calling of the meeting, and then went on to point out the methods of registration at present in working at the different hospitals, which were as follows:—On the medical side—1. Cases recorded by the registrar (two hos-

pitals); 2. Cases recorded by house-physicians, the index alone being kept up by the registrar (four hospitals); 3. Cases taken by students subject to supervision by the registrar (five hospitals). On the surgical side—1. Cases recorded by the registrar (six hospitals); 2. Cases taken by students, supervision by registrars (five hospitals). He then proceeded to draw attention to the points of merit or the faults of the different systems, laying special stress on the want of control over students in those instances in which the students took a part in the case-taking; and also the difficulty of obtaining access to the notes under the circumstances in which the case books or notes were not kept either in the ward or by the patient's bed. It was also shown that the Pathological reports were kept in three different ways. 1. A report of the post mortem being added to the ward notes. 2. An abstract of the ward notes being attached to the Pathologist's report. 3. The Pathologist's report entered in a separate book, reference only being made to ward notes by vol. *x*; p. *y*. The issuing of annual reports was then briefly alluded to, and their direct bearing on the accuracy of the ward notes. It was suggested that the registrars should form themselves into an association which should hold meetings two or three times a year, at which any alterations or improvements in the method of registration could be discussed, and the attention of registrars drawn to the working out of any special point.

Dr. MAHOMED (Guy's) considered that it would be impossible to establish anything like a uniform system of registration, and of the different methods now at work he was inclined to think that one the best in which students were allowed to take part, but at the same time he was strongly in favour of registrars having complete control over the students.

Mr. SYMONDS (Guy's) was of opinion that it would be better to allow students only to keep up the daily records of the cases, and that the actual taking of the case in the first instance should be the duty of the registrar. With regard to the suggestion of forming an Association of Registrars, he considered it a good one, but feared that there would be a possibility of registrars being overburdened with work, as it was likely that the Pathological or some other Society might send down a request to the Registrars' Association to investigate some point.

Mr. MULLEN (London)—who stated he had experience of the two methods of registration: (1) in which the registrars record the case; and (2), in which the students performed those duties—was strongly in favour of the first method, and objected as strongly to the registrars having any control or connexion with the students in the work of note-taking.

Mr. CRIPPS (St. Bartholomew's) also preferred that the registrars should record all cases, and stated that at St. Bartholomew's the surgical registrars had no difficulty in recording two hundred cases each. He alluded to the faulty method of indexing diseases generally employed, and suggested that if an association of registrars were formed that this should be one of the first points to which attention be given.

Dr. DUNBAR (St. George's), Dr. GABBETT (London), and Dr. WILLCOCKS (King's), also took part in the discussion, the general impression being that it would be impossible to establish a uniform method of registration, but that an Association of Registrars would go a long way in mitigating the present evils, in that they could make suggestions for the working, or direct attention to any special point.

Mr. HOWLETT then proposed, "That an Association of metropolitan and provincial hospital registrars be formed, which shall hold occasional meetings for the general supervision of the work of registration." Mr. CRIPPS seconded the motion, which was carried unanimously.

The meeting then adjourned with a vote of thanks to the chairman.

The following hospitals were represented at the meeting—viz., St. Bartholomew's, St. George's, Guy's, King's College, London, Middlesex, University College, and Westminster. The first meeting of the new Association will be held at King's College Hospital, on Wednesday, November 3rd, at 8 P.M., to elect officers and establish a uniform index.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—Mr. Robert Lawson has obtained the Entrance Scholarship in Natural Science of the value of £100, and Mr. Herbert Lankester that of £60.

"Audi alteram partem."

HYPODERMIC INJECTIONS OF MORPHIA IN CHOLERA.

To the Editor of THE LANCET.

SIR,—In justice to the whole medical profession in India, I hasten to make public what I know of our experience of the above-named treatment in Asiatic cholera, as Mr. Hardman in his exceedingly interesting communication to your columns of the 2nd inst. seems to desire. I believe I was the first to try so obvious a mode of treatment in 1865, with the *post hoc* result that six cases out of fourteen got well. This you were good enough to publish in THE LANCET in 1872, and was first made known in Deputy-Surgeon-General Murray's compendious "Report" on Cholera. The average success is scarcely above the usual one in severe epidemics. These cases, also, were all of very severe type. But most often deaths were, as usual, in the secondary fever stage. How far this was the result of the treatment is uncertain, for fatal *coma-vigil* is a common ending in the malignant disease. Reaction took place in more than half the fatal cases, and I have always found the morphia injection favour it. But it is of much more interest to inquire whether the cases cited by Mr. Hardman with so much careful accuracy were cases of choleraic diarrhoea or rather (for the term is now abolished in official reports) of the diarrhoea stages of true cholera. For if "choleraic diarrhoea" mean simply a diarrhoea bearing a certain resemblance to cholera, and that is the most likely to be the case, morphia is the remedy which Mr. Hardman paints it to be. Still, although it is almost certain that diarrhoea simply resembling cholera cannot become such, nevertheless morphia (of course, hypodermically), by diminishing exhaustive discharges and obviating blood-thickening, and perhaps as a stimulant, &c., practically, and combined with other remedies, is found to be one of our chief resources. It has been used, abandoned, and returned to over and over again. But it is not an antidote to the cholera poison (or force, as some thinkers have it in the sense that heat and electricity are forces). Mr. Hardman well and truly describes the features of diarrhoea resembling cholera, but unconsciousness is noted in the collapsed stage of only three out of the thirteen. Again, cramps were only noted in five cases. Cramps are also seen in bilious diarrhoea, &c., and collapse (mentioned in three of the cases) in many diseases. Rice-water stools, which are quite *sui generis*,¹ are only mentioned in one case. The purging in three others is either "watery and colourless" (this is quite different from rice-water) or "yellowish," the other dejecta apparently were merely loose, "violent purging," &c. None of the cases presented the peculiar burning anguish over the præcordia, nor the suppression of urine, so universal in cholera. But whether the disease were cholera (at least in some of the cases) or not, the treatment does Mr. Hardman great credit. The reason why it is not so successful in malignant cholera is that it is not alone "the purging that kills," I fear; I say it with the utmost deference. It is not, at all events, the mere loss of water and salts that kills, for intravenous injections have been extensively tried since Mr. Hamilton's experiments in Edinburgh in 1833. I injected large quantities of warm water subcutaneously, not into the veins, after the plan suggested by a surgeon in Bengal. As in Hamilton's cases, every symptom disappeared only to return and kill before we had time or heart to inject more. I think I sent you the cases. It is true this man had long been troubled with chronic bronchitis and embarrassed heart. Nevertheless, as I saw a gentleman who never gave opium lose all his cases (16), and as the most wonderful recoveries sometimes follow a full opiate, purging must be allowed to be a factor in assisting the fatal collapse. If opium simply locked up the poison and caused subsequent uræmia, then all the cases taking opium would get worse and die, in a severe type of the disease, which is, as shown by Macnamara and most unprejudiced writers, utterly at variance with experience. At the very time that the anti-sedative practitioner lost all his cases a col-

league saved two "without treatment," he said, but when hard pressed, he allowed that "of, course, that they had had opium at the first onset." I fear that the undue dread of this medicine has made us unduly sparing of it. I have known a gentleman severely reprimanded for using it. This was in the Madras Presidency, he told me. It seems almost incredible. A soft pill (to ensure its retention by gravity, Wylie's) of calomel should be given with any injections, to encourage the depurative functions. Chloral cures cramps, but does not relieve capillary spasm in the lungs, nor, apparently, does nitrite of amyl (not extensively tried). Injection of ammonia, if strong enough to do good, causes such terrible sloughing in cholera as to be practically useless, and in any case does not seem to have had a pronounced success. I saw numbers die, after reaction, under its use. I injected bromide of ammonia late in one case (but it was a relapsed one) without appreciable effect. Diuretics, &c., must never be neglected. The cold douche helps reaction. I have not seen a case subsequently. Since my first experience as resident medical assistant in a temporary cholera hospital in England I have seen five epidemics in India, besides constant sporadic cases, which must be my excuse for troubling you, and writing too dogmatically.

I beg to remain, Sir, yours truly,

C. MACDOWALL, F.R.C.S.E., &c.

Bombay Army.

INTESTINAL OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—I have just read Dr. Lambart's case of intestinal obstruction, published in your journal of June 26th, 1880; and think that that gentleman will not object to an account of the experience of an Indian medical officer on the same subject, which I shall make as concise as possible.

Subsequent to my commencing practice in India, and before I had read Dr. Brinton's monograph on this subject—i.e., from 1859 to 1865—very many cases of intestinal obstruction, including intussusception, came under my care, as this disease is very common among native troops, who eat only once or twice daily, and then are apt to gorge themselves with, often, indigestible, badly cooked food. Between 1859 and 1865 my treatment for such cases was castor oil internally—both by mouth and, mixed with a pint or so of warm water, by rectum—followed by calomel and opium, with, externally, fomentations, &c., and when everything else failed injections of air through the rectum. In most of the cases there was swelling—generally localised to right side of abdomen—or when there was, as often happened, general tympanitic distension of the abdomen, this enlargement was more prominent and defined on one side of the abdomen than on the other, which side was also the almost exclusive seat of the pain. In some cases blood was passed per anum, but frequently none was thus passed; vomiting soon ensued in most cases, and was, after a time, of a faecal character; all of such cases proving fatal—i.e., cases with faecal vomiting. In the class of cases now before my mind the symptoms were quite different from those observed in colic, and fever set in almost with the pain, which was always increased by the slightest pressure.

In 1865 I read Dr. Brinton's monograph, carefully studying the (1) mechanism of the disease (i.e., its natural history), its (2) pathology and (3) treatment, as is so beautifully, clearly, and ably described in the work referred to; and, as the monograph can be easily had at any medical bookseller's in England, I need scarcely refer further to the above three points here. Of course, in the treatment solid opium by the mouth, pushed to its most extreme limit compatible with safety from narcotism—so as to completely paralyse the affected part of the bowel—is the main principle of the treatment, as thus rest and time are allowed sufficient to permit of the invaginated portion of bowel sloughing off and of a break in continuity being prevented by the lymph, which has been previously thrown out, gluing together the upper and lower ends of the affected portion of bowel; the slough being carried off with the other contents of the bowel, and the continuity of the tube being restored by the removal of the invaginated portion thus shed. As in Dr. Brinton's cases, I found from thirty to forty days necessary for this process to take place, and in the interval only concentrated fluid nourishment in small quantities at a time was given, and by the mouth also. From twelve to twenty

¹ I think it was Sir Joseph Fayrer who produced in dogs something like rice-water dejecta by acute poisoning with arsenic.

grains of solid opium were sometimes given in twenty-four hours, although, generally, a smaller quantity sufficed. After a few weeks the patients complained of the pills (opium) purging them, which was really because about then large black and often fetid stools were passed. In fact, the first stools were remarkably copious with large scybala, for no other drug was given, and I cannot, now, have treated less than two hundred such (as the latter ones) cases, not one of which has terminated fatally. Other medical officers—several years since, before Dr. Brinton's work was generally read—have at my suggestion tried this treatment in similar cases and with equal success.

I am, Sir, your obedient servant,

CHARLES P. COSTELLO,

Surgeon-Major, Bengal Medical Department,
Officer in charge, 1st Goorkha, L.I.

Jagdallack Kotal, Afghanistan, July 27th, 1880.

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—I hope I may be excused if I decline to reply to the attack made upon me by Messrs. Hickinbotham and Tait in last week's LANCET. In Birmingham, where all of us are known, there is no need for reply. To readers at a distance I may say that I cannot hold myself responsible for the failures of Dr. Hickinbotham and Mr. Tait, who unite with curious eagerness to testify that *they* can do nothing with a remedy which in other hands has proved itself valuable. As it seems that their experience extends over a very short period, it is not likely to be accepted as weighty, still less as conclusive.

With your permission I shall, from time to time, continue to report facts, which come under my observation; and I shall venture to ask candid members of the profession to do the same, as the truth can be established only by experiments widely conducted, undertaken without prejudice, and extending over a sufficient period to afford a real test of the value of Chian turpentine in cancer.

I am, Sir, yours obediently,

Birmingham, October 10th, 1880.

JOHN CLAY.

THE HEALTH-RESORTS OF THE HARZ MOUNTAINS.

(From our *Roving Correspondent*.)

WHEREVER fresh air, temptations towards wholesome exercise and abundant opportunities for the relaxation of the mind are to be found, there may health also be met with, and since these health-giving opportunities all exist in the Harz, together with some few more special aids towards the recovery of tone, lost either through disease or undue application to professional work, we propose to give a brief sketch of the chief characteristics of a district which is not perhaps one of those which is most intimately known to British travellers.

The Harz is easily reached, and if the traveller be not afraid of a thirty-six hours' voyage, I should advise him to follow my example and go direct from London to Hamburg by steamboat. If the weather be favourable no better beginning to a holiday can be imagined than the enforced idleness, the sunlight, and the fresh air, which are the concomitants of a lucky voyage, but I say nothing of the horrors of an overfilled packet in rough weather, when ports are closed and the unhappy passengers spend their time in the stifling atmosphere of a prison lazaretto, in which that "chance of being drowned" of which Dr. Johnson spoke becomes in no short time a consummation devoutly to be wished. The visitor to the Harz will use his own judgment in such a matter, for it can also be approached with great readiness *viâ* Calais and Cologne, or by half a dozen other routes, of which he can take his choice. From Hamburg to Brunswick is but a short journey, and from the latter place to Harzburg, the most north-westerly point in the mountains, where accommodation is to be found, may figuratively be spoken of as "a mere step."

The Harz is a mountainous forest, about fifty miles long and twenty miles wide, running obliquely from the north-

west to the south-east. It rises with strange abruptness from the sandy plain of North Germany. Round it is a girdle of railway which connects the important towns of Goslar to the west, Halberstadt to the north, Halle to the east, and Nordhausen to the south. From the northern half of this iron girdle run branch lines southward which just touch the mountains at Clausthal, Harzburg, Wernigerode, Blankenburg, Thale, and Ballenstedt, and serve to carry travellers and bring away the wood, iron, lead, manganese, silver, and other minerals which the district produces. A railway is being talked of to go right through the Harz from Nordhausen to Ballenstedt, but this enterprise is as yet in an embryonic condition, the surveyors having only just commenced their work.

I can add very little to the two words used to describe the Harz at the beginning of the last paragraph. It is a "mountainous forest." The mountains are none of them very high; the famous "Brocken," which towers considerably above its fellows, being about the height of Snowdon, and being almost the only one which is not wooded to its summit. The forest is everywhere surpassingly beautiful, and for the variety of foliage to be found therein it greatly excels the Black Forest, and rivals the lake districts of Cumberland or our own New Forest. The oak, beech, birch, and mountain ash are to be found in great quantities; and pines, it is needless to be said, are everywhere. There are no lakes, but rippling mountain torrents make music upon every side. The soil is almost everywhere porous, being composed of granitic and shaly detritus; and this fact, coupled with the universally undulating nature of the ground, ensures that the effects of rain are not of long duration, and that out-of-door exercise is usually possible the moment that it is dry overhead. As in all northern mountainous districts, rain is not uncommon, but it is neither so frequent nor so severe as always is the case at Killarney, and nearly always in Cumberland. The absence of lakes, the insignificant size of the rivulets, and the great number of open-air restaurants scattered here and there all testify to the fact. The two great industries of the district are wood-cutting and mining, the latter having its headquarters at Clausthal. The climate is a temperate one, with perhaps rather more sun and certainly less rain than we are accustomed to at home. The almost entire absence of any of the more delicate fruits (even in September) and vegetables from the country markets is an indication that we are in a country verging on the barren north, while an occasional glimpse of a snow-plough by the roadside, or of a disused sledge hanging from the beams of an inn coachhouse, serve to remind one that here the rigours of winter are such as we in England have no acquaintance with.

Before going into details with regard to any one of the resorts of the Harz mountains, it may be well to state what are the good and bad points (from the point of view of the traveller and health-seeker) of the district generally. To take the good points first—we may say, *imprimis*, that the inhabitants appear to be universally obliging, scrupulously honest, and deferentially polite, and I feel sure that a lady might travel throughout the district without suffering molestation or incivility of any kind. The roads are everywhere magnificent, and well-kept footpaths for the convenience of visitors lead to all the most picturesque and interesting points. The average German does not appreciate scrambling over rocks and boulders. Quiet contemplation and rumination are his natural occupations, and he prefers to take his pleasure and his ease together, and is ready to climb to the summits of the hills provided he can do so leisurely and comfortably without having to fling away his cigar, or being obliged to discontinue his disputations or his ruminations for the sake of looking after the safety of his limbs. The points of view are all railed in, and finger-posts are so plentiful that in the depths of the forest it is not possible to lose one's way. This ample provision of paths is a great boon to ladies and persons who are not blessed with a great amount of physical vigour. Even the most determined pedestrian or climber is not allowed in the Harz to run the risk of exhaustion for want of food, for wherever he is likely to be tempted to press forward his footsteps, there he is equally sure to find the inevitable restaurant and gasthaus; and, indeed, the lively German keller, flitting to and fro with pyramids of glittering golden beer, seems as native to the soil as the grasshopper or the dragon-fly. The omnipresence of "refreshment" is a kind of thing to which in England we are apt to apply the term "cockney," but the cockney is often a practical indi-

vidual, and some of his habits are upon occasions acceptable. It often seems, however, in Germany, as if mine host were the absolute proprietor of the beauties of nature, and that those visitors who are not endowed with a perennial appetite and an insatiable thirst were scarcely welcome.

The drawbacks to travelling in the Harz, especially to invalids, are mainly two, and these two are most important—viz., the hotels and the food.

In the first place, it is imperative that the hotel selected by a traveller in search of health should be quiet, so that sound sleep with an open window shall be possible. How rarely this is to be found every traveller knows to his sorrow. The hotels generally abut upon the village street, and the village street is always paved—or rather, we should say, covered—with huge boulders roughly placed together. Along the streets a country timber waggon will make a noise like thunder, and a light empty truck drawn by galloping dogs will produce a sound like a thousand policeman's rattles "sprung" together. He who leaves the noise of London to enjoy the peaceful quiet of a German village will often find that he has by no means improved his condition. As the villagers begin to stir soon after four o'clock in the morning, our traveller will perhaps seek his couch at an early hour; but floors and walls being thin, and the houses being to a great extent constructed of wood, he will find that sounds of various kinds, and all equally disturbing, find their way to his heavy pillow. The guests downstairs are drinking a last "toast," and growling a last pæan in praise of Vaterland and Kaiser, and when this is finished the inhabitants of the rooms on either side seek their respective beds with no little lumbering, and stamping, and clearing of throats. Then the arrivals by the last train have to be stowed away, and their boxes have to be carried up creaking stairs and along resounding passages, and then when the last "gute nacht" has sounded, and the last door has slammed, the worried traveller may sink to rest for three or four hours' quiet repose, always provided that the big dogs of the village do not take a fancy to bay the moon, or the cats of the neighbourhood be not minded to go a-courting. If it be laid down as a rule that voyagers should avoid hotels which abut upon the village street, or which are situated too near to a railway station, I fear their choice will be small. Another common and very serious defect of the hotels in the Harz is the "sanitary arrangements," if such a term can be applied to the pestilential privies which are to be found in all but the very best houses.

Next, as to the food. Good coffee and bread, excellent butter and eggs, and first-rate beer are to be got everywhere, but a wholesome, nutritious, and appetising dinner is scarcely to be got anywhere. Potatoes and grease in plenty, huge lumps of cabbage, heaps of coarse beans, compressed masses of chopped skin and sinew, to which no scrupulous person would give the name of a "rissole," added to dabs of veal and coarse beef swimming in rich oily gravies, form the staple of the table-d'hôte at all except a very few of the best hotels. Such dinners are cheap no doubt, but there is equally no doubt of their nasty and indigestible qualities. If the Germans could restore to the French their two ravished provinces, and take in exchange the knowledge of, and the talent for, the culinary art, which their neighbours possess, how very much the best of the bargain they would have.

Next, to come to particulars, Harzburg has claims to be considered a "Bath" and a health-resort, and its popularity is very greatly on the increase. It is well provided with lodging-houses and hotels; and of one of them, the Actien Hotel, which is the property of a limited company, I can confidently say it is admirably situated, and its accommodation fully equal to that which is to be found in the very best Swiss hotels. I expect that the example which has been set in Harzburg, in the matter of hotels, will be followed in other localities in the Harz. Harzburg itself is a most picturesque and delightful spot, standing at the entrance of the Radau Thal, and some seven hundred feet above the sea-level. On every side of it save to the north is the undulating forest, intersected with pleasant paths and drives. It is a point from which numberless excursions can be made, and every facility in the form of carriages, ponies, and guides is here in abundance. It has also a well-known brine spring, the so-called Julius Hall, containing rather more than six per cent. of chloride of sodium, besides other ingredients; and there is a bath-house of considerable size, where not only soot (or brine) baths may be had, but also many other varieties of baths which have

been devised by German ingenuity—such as wave baths, pine baths, douche and shower baths of salt or spring water, vapour baths, inhalations of all kinds, and, lastly, malt baths (!), which I conclude is the last new thing. Being a real "Bath," Harzburg has also the resources proper to such a place—viz., a capital Kurhaus, a very good band of musicians, a first-rate promenade in the shade of a picturesque plantation of oaks, and, lastly, that collection of booths for the sale of nicknacks and trumpery without which no continental bathing-place would be complete.

Thale, which is at the eastern end of the Harz, is certainly the most picturesque spot in the whole of the district, and is probably more frequented than any. The rocky valley of the Bode can scarcely be excelled for grand magnificence and a wondrous intermixture of bold, rugged, and fantastic rocks, with soft and varied foliage, and is, I think, as picturesque a spot as it is possible to conceive. Here, too, is fair hotel accommodation, and here also is a brine bath, called the "Hubertus Bad," to which a certain number of patients repair annually to do a "cure." Thale belongs, however, rather to the tourist than the invalid, and on a Sunday especially trains come loaded with excursionists from the neighbouring cities of Magdeburg, Halberstadt, and Quedlinburg.

At Suderode, a pleasant village not far from Thale, on the southern slopes of the hills and overlooking the plain, is also a brine spring, which is used to some extent for bathing purposes.

Other picturesque spots which are much visited in summer are Ilsenburg, at the entrance of the lovely Ilsethal, Haserode, a village close to Wernigerode, and Blankenburg. In addition to its brine springs the Harz can boast of a chalybeate spring of some notoriety. This is at Alexisbad, which is situated high in the mountains, nearly midway between Ballenstedt and Nordhausen. The situation of Alexisbad is charming, and for quiet, rural, and picturesque qualities it is not excelled by any watering-place I know. The water is a strong chalybeate, but I was unable to ascertain its exact composition. Alexisbad, notwithstanding its great natural beauties and powerful medicinal spring, seems to have passed the zenith of its fame. It was founded more than sixty years ago by one of the Dukes of Anhalt, and, with the aid of a gambling table, it obtained a certain amount of fashionable notoriety. I fear, however, its sun has nearly set. I arrived there on Sept. 15th, which is by custom the last day of the season. The "season" had certainly ended at least the day before, for I was the sole guest at this once fashionable resort, notwithstanding that the weather was still warm and summery. The healing fountain was locked up, and I only managed to taste its water by committing a pseudo-burglary. I walked through the bath-house unchallenged and alone, and noted the ample provision for bathers who had taken their departure. I paced alone the floor of the prim old-world white and gold ball-room at the Kurhaus, while my fancy took me back some sixty years to the time when the reigning beauties of the Court of Anhalt, with high-waisted dresses and with powdered hair, trod its smooth floor to the stately measure of a minuet; I peeped into the billiard-room where formerly clusters of gamblers had been grouped around the roulette table; I walked to and fro on the excellent promenade where was never a soul but myself; and finally I sat down in state in the biggest room of the best hotel to a table-d'hôte of two persons! Assuredly the Alexisbad season was at an end; and from some conversation with the natives, I gathered that of late years the number of visitors had gradually declined. During the afternoon this discarded shell of fashion was visited for a few moments by a party of royalty from the neighbouring Residency at Ballenstedt. Returning from a walk, I found a couple of Court carriages, with outriders and servants in gay liveries, in front of the Kurhaus, while their royal occupants were taking a short and stately promenade in the well-gravelled avenue, and listening to the final efforts of the Alexisbad band, stationed for the occasion on the summit of a high rock in the neighbourhood. A few strips of white and green bunting (the Anhalt colours) fluttered from the top windows of the hotel, bouquets were presented, and the Royal party of eight returned the salutations of about as many onlookers; but, alas, the royal carriages were soon refilled, the strains of the band died away, and the last faint spark of life died out in Alexisbad. There appear to be two possible causes for the waning popularity of this bath; one is that the pretty stream which

waters the valley in which it stands has been fouled and rendered turbid by some lead-works a mile or so higher up, and another is that there is a good deal of stagnant water, o'ergrown with duckweed, and no little swampy ground in the immediate neighbourhood of Alexisquelle itself. The want of direct railway communication and the competition of other and more fashionable resorts, &c., are also doubtless answerable in some degree for the small number of visitors who come to Alexisbad. Nevertheless, it is a most lovely spot, and when the railway finds its way there, as it will do in a few years, it will only require a master mind and a little energy and wise expenditure to make Alexisbad one of the most popular chalybeate springs in Europe.

PARIS.

(From our own Correspondent.)

AN unpleasant incident occurred at the last meeting but one of the Academy of Medicine. After a speech from M. Jules Guérin, in which that gentleman objected, both as a savant and as a ratepayer, to the Government grant awarded to M. Pasteur, the latter replied in a violent manner, and in a tone which was supposed by M. Guérin to impugn his scientific honour. The most objectionable phrase was as follows:—"When in the name of clinical principles a man has proposed to aspire up to the surface of wounds by means of an india-rubber cap, some tubes, and a pneumatic pump, he is capable of anything (*on est capable de toutes les audaces*), and finds the careful and correct experimenter, who will not announce his method to the world before being able to demonstrate it, singularly simple. This is a question of scientific honour. I shall not risk compromising mine by too hasty publication for the satisfaction of gratifying the indiscreet and unhealthy curiosity of M. Guérin." M. Guérin was anxious to reply, but on the motion of Baron Larrey the sitting was immediately adjourned. What followed is not published in the official bulletin of the Academy, but may be described as a "row" between the two savants. After making a vain attempt to "go for" M. Pasteur, and unrestrainedly expressing his opinion about his colleague's veracity, M. Guérin retired. The following day brought his resignation as a member of the Academy of Medicine, and negotiations for a "meeting." M. Pasteur then placed himself in the hands of two friends, and by their intervention the matter has been arranged satisfactorily. At the last meeting a pacific letter was read from M. Pasteur, and it was announced that M. Guérin had withdrawn his resignation.

The smells of Paris have taken up the attention of the Municipal Council since the members have returned from the holidays. As usual, there is a great deal of talk but very little action. At a recent meeting, M. Alphanand attempted to make out that there had in reality been very little to complain of, and that the whole outcry against the administration had been the result of a fictitious and political agitation on the part of an ill-disposed Press. Unfortunately for the public authorities, they have a very powerful opponent in this matter in the shape of M. Francisque Sarcey, the eminent critic, who happens to reside in one of the least fragrant quarters. He deals with M. Alphanand's statement in a recent number of the *XIXième Siècle*, and some of his statements are worth quoting textually:—

"M. Alphanand tire de cette unanimité même un argument contre la presse: Ce sont les journaux, dit-il, qui ont envenimé la question! Ce sont eux qui ont fait tout le mal! A force de crier contre les mauvaises odeurs, ils ont fini par persuader aux Parisiens et même aux étrangers, que ces mauvaises odeurs existaient véritablement. Jamais, avant ce concert de criailleries, les Parisiens ne s'étaient aperçus que ça puait chez eux. Les voilà aujourd'hui amentés contre cette prétendue infection. A qui la faute? A ces incorrigibles bavards de journalistes. Pour un peu, Alphanand dirait volontiers que c'est nous qui avons la malice de puer, pour le plaisir de donner du souci à l'administration. Depuis une huitaine de jours, ça puait tous les soirs dans mon quartier, et ça puait ferme. Un soir, notamment, ça puait si fort que je me suis vu obligé de fermer les fenêtres, et ça n'en puait que davantage. Ma foi! le lendemain matin j'avais un article à écrire; j'ai l'habitude

d'entretenir nos lecteurs de tous les sujets qui m'intéressent, et juste à l'heure où ils m'intéressent et comme ça puait dans mon quartier, j'ai tout de suite dit avec ma bonhomie ordinaire: Ah! mes enfants, comme ça pue dans mon quartier! Non, mais vous n' imaginez pas comme ça pue dans mon quartier. Cette phrase m'est témoin que je ne m'étais point demandé, avant de pousser ce cri de douleur, si M. Andrieux avait pris un arrêté la veille, ni même si M. Andrieux était préfet de police. Je disais: Ça pue, parce que ça puait, avec l'ingénuité d'un homme qui se bouche le nez quand ça pue, en s'écriant: mon Dieu! que ça pue!"

The *Charivari* of last week, alluding to the same subject, represents a country gentleman in the act of inhaling the emanations from a heap of manure. "What are you doing there, papa?" asks the son, "Going into training for a visit to Paris," is the reply.

Obituary.

WILLIAM MOORHOUSE, M.R.C.S., L.R.C.P. Ed.

DR. MOORHOUSE, whose death we announced last week, was a student at Edinburgh and St. Bartholomew's Hospital, and after passing his examination at the College of Surgeons went to India; subsequently he became house-surgeon at the Royal Free Hospital. After a short interval, occupied in assisting in private practice and at the Liverpool Infirmary, he commenced practice in Ellesmere, and soon became a great and universal favourite in the neighbourhood.

There was much in his character and disposition to cause him to be beloved by the generous and kind-hearted people of Shropshire, who, whether rich or poor, found that they had a sympathising friend in James William Moorhouse. He was a rigid observer of medical etiquette, and invariably acted with frankness and generosity towards a brother practitioner. He was a man of extraordinarily active habits. About two years ago his constitution showed symptoms of giving way, and on September 18th, after coming from a long journey, he was suddenly seized with a fatal attack of apoplexy, which terminated his existence in about two hours. The grief of his friends cannot be told; but the sorrow of his patients and neighbours found expression in the respect paid to his memory, as the mournful procession passed through the town on the day of interment, by the shops being closed and every other mark of regret manifested.

SIR WILLIAM LINTON, K.C.B.

WE regret to announce the death of an old and distinguished army surgeon. Sir William Linton, K.C.B., M.D., expired after a very short illness from apoplexy on Saturday last at his residence, Skairfield, Dumfriesshire. He was a graduate of Edinburgh University, and entered the Army Medical Department in 1826. He served in Canada, the Mediterranean, and the West Indies, and in 1848 was made staff-surgeon of the first class. In the Crimea he held the post of Deputy-Surgeon-General of the First Division, and was in medical charge of the General Hospital, Scutari, after the termination of the campaign. In 1857 he was promoted to the rank of Inspector-General of Hospitals, and shortly afterwards was ordered to India as Principal Medical Officer of the European Army. He acted in this capacity throughout the mutiny, and for his services was advanced to the Knighthood of the Bath, having been made a Companion of the Order in 1856. In 1859 he was appointed Honorary Physician to Her Majesty. Sir William, who was never married, was placed on the retired list in 1863.

At an inquest held on Wednesday at Birmingham, on the body of Charlotte Stephens, widow of a jeweller, the Borough Coroner commented (says the *Globe*) strongly upon the course the police had adopted. The deceased was found lying in the street, and a policeman, supposing she was under the influence of drink, locked her up on a charge of drunkenness, but early the next morning she was removed to the hospital, where she died the same evening. The post-mortem examination proved that death resulted from apoplexy, and the jury, in returning a verdict to that effect, expressed an opinion that the woman ought to have been examined by a medical man before she was locked up in a police cell.

THE CRISIS AT GUY'S HOSPITAL.

At the moment of going to press the rumour reaches us that the Court of Governors, at their meeting on Thursday evening, accepted the letter of withdrawal addressed to them by the medical staff.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 7th:—

Atterbury, Walter, Acacia Villa, Oppidans-road.
Davis, Edward, Euston-square.
Jay, Melville Richard Hindmarsh, Adelaide, S. Australia.
Nance, Henry Chester, Eccleshall, Staffordshire.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Henry Green, St. Mary's Hospital; Simpson Powell and Chas. Henry Whitcombe, King's College Hospital; Robert Williamson Shelley, Charing-cross Hospital.

DR. FAUSSETT, late medical officer of Clontarf Dispensary Committee, has been allowed a superannuation of £50 per annum.

ACCORDING to the report of the cattle inspectors of the county of Lancashire, pleuro-pneumonia and swine fever continue to spread. Meanwhile all available precautions seem to be taken to check the ravages of the diseases.

At the quarterly meeting of the directors of the Compassionate Branch of the Naval Medical Supplemental Fund, on the 12th inst., Dr. H. J. Domville, C.B., Inspector-General, in the chair, the sum of £65 was distributed among the several claimants.

GUY'S HOSPITAL MEDICAL SCHOOL.—The open entrance scholarship of 125 guineas in science has been awarded to Mr. H. W. Pigeon, and that of 125 guineas in Arts to Mr. R. Moody Ward; Mr. G. E. C. Anderson *proxime accessit*.

EAST LONDON HOSPITAL FOR CHILDREN.—The fifth anniversary festival in aid of this charity was held, under the presidency of the Lord Mayor, on Wednesday evening. The aggregate number of patients treated since the foundation of the hospital amounts to 85,961. There was last year, we are sorry to learn, a falling off in the receipts to the extent of £1374—a state of things which we trust will be found to have been improved by the time the next festival comes round.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES.

—The late Mr. John Skirrow Wright, of Birmingham, bequeathed £200 each to the General Hospital and the Queen's Hospital, Birmingham. By the will of Mr. George Checkland, late of Hawkswick, Herts, the Leicester Infirmary receives £100, and the Dispensary of the same town £50. The late Mr. John Andrew Jones, of New York, bequeathed 5000 dollars to the Dreadnought Hospital, Greenwich. The Brixton, Streatham-hill, and Tulse-hill Dispensary has become entitled to £50 under the will of the late Mr. John Holloway, of Brixton-road. Miss Jane Burnett, of Oldmeldrum, has left the residue of her estate to the Aberdeen Royal Infirmary.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

BATTERBURY, R. L., M.B., has been appointed Certifying Factory Surgeon for Berkhamsted.
BRUCE, R. C., M.B., C.M., has been appointed House-Surgeon to the Edinburgh Royal Maternity and Simpson Memorial Hospital.
CLARKE, J. A., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer of the Levensden Schools.
ERSON, W. R., L.F.P.S.G., L.S.A.L., has been appointed Medical Officer and Public Vaccinator for the Lindley-cum-Quarby District of the Huddersfield Union, vice F. C. Ellerton, resigned.
GOODE, C. F., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Brighton and Hove Lying-in Institution, vice Freeman, resigned.
HARRIS, F. W. H., M.R.C.S.E., has been appointed Assistant Medical Officer to the Suffolk County Asylum, vice Tate, resigned.

HEATH, G. Y., M.B., L.R.C.P.Ed., M.R.C.S.E., has been appointed Consulting Surgeon to the Newcastle-on-Tyne Infirmary, on resigning as Surgeon.

HUNT, J., M.R.C.S.E., has been elected Acting Surgeon to the Children's Hospital, Birmingham, vice Mr. G. H. Evans, resigned.
JAKINS, P. S., M.R.C.S.E., L.S.A.L., has been appointed Clinical Assistant to the Western Ophthalmic Hospital, vice Bird, resigned.

KELLETT, R. G., L.K.Q.C.P.I., L.R.C.S.I., has been reappointed Medical Officer of Health for the Halstead Urban Sanitary District. £25 per annum.

KEMPE, J. A., M.R.C.S.E. & L.R.C.P.L., has been appointed Assistant Demonstrator of Anatomy at University College Hospital.

MACDOWELL, F. V., L.R.C.S.I., has been appointed Medical Officer to the Baltinglass Union Workhouse and Fever Hospital, vice Seymour, deceased.

MAYLARD, A. E., M.B., B.Sc., has been appointed Demonstrator of Anatomy at Guy's Hospital.

PALMER, H. L., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Llanllwchaearn District of the Newtown and Llanidloes Union.

PULLON, H., M.B., C.M., has been appointed House-Surgeon to the Edinburgh Royal Maternity and Simpson Memorial Hospital.

RUTHERFORD, R. L., Senior Assistant Medical Officer, Durham County Asylum, has been appointed Assistant Medical Officer to the Devon County Asylum.

STEELE, R. L., L.R.C.P.Ed., M.R.C.S.E., has been appointed Honorary Medical Officer to the King's College Hospital Convalescent Home, Hemel Hempstead.

WATSON, C., L.K.Q.C.P.I., has been appointed Medical Officer to the Kildare Dispensary District of the Naas Union, vice Kehoe, deceased.

WHITE, R. P., M.B., C.M., has been appointed House-Surgeon to the Halifax Infirmary, vice Hammond, resigned.

WHITE, W. H., M.B., has been appointed Resident Medical Officer to the Evelina Hospital for Sick Children.

Births, Marriages, and Deaths.

BIRTHS.

ADAMS.—On the 28th ult., at 42, Russell-road, Kensington, the wife of W. Stanley Adams, M.D., of Forest Lodge, Hongkong, of a son.
BUCHANAN.—On the 3rd ult., at Lucknow, the wife of Surgeon-Major Buchanan, Army Medical Department, of a son.
HUNTER.—On the 4th inst., at Norfolk-crescent, Hyde-park, the wife of W. Guyer Hunter, M.D., F.R.C.P., Hon. Surgeon to the Queen, Surgeon-General H.M. Indian Army, of a daughter.
PHIBBS.—On the 29th ult., at Sutherland-gardens, W., the wife of Dr. R. Featherstone Phibbs, M.R.C.P., of a son.
SPANTON.—On the 9th inst., at Chatterley House, Hanley, Staffordshire, the wife of W. D. Spanton, M.R.C.S.E., of a daughter.
THURSTAN.—On the 23rd ult., at The Hollies, Windmill-road, Croydon, the wife of E. Paget Thurstan, B.A., M.B., of a son.

MARRIAGES.

EDMOND-FRASER.—On the 13th inst., at 21, Chalmers-street, Edinburgh, by the Rev. R. Macdonald, D.D., Free Church, North Leith, and the Rev. R. G. Balfour, Free New North Church, Edinburgh, John Edmond, Advocate, Aberdeen, to Evangeline Mary, eldest daughter of Surgeon-General J. Fraser, M.D., C.B., Honorary Physician to the Queen.
HINE.—On the 30th ult., at the Wesleyan Chapel, Baldock, Herts, Alfred Leonard Hine, M.R.C.S.E., L.R.C.P., third son of the late Joseph Hine, of Newnham, Herts, to Helen, second daughter of Thomas Hine, of Baldock.
ROSE-CLARK.—On the 6th inst., at St. Stephen's Church, Westbourne-park, W., by the Rev. T. J. Russell, M.A., Vicar (one of Her Majesty's Chaplains), William Rose, F.R.C.S., M.B. Lond., to Mary Anne Cooper, youngest daughter of Robert Clark, Solicitor, of Chepstow Villas, W.
SMITH-HIGGS.—On the 6th inst., at All Saints' Church, Clapham, by the Rev. A. G. Girdlestone, M.A., Sydney Lloyd Smith, F.R.C.P.E., M.R.C.S.E., L.S.A.L., &c. &c., second son of W. F. Smith, M.P.S., of Walworth and Brixton, to Sarah, eldest daughter of James Higgs, of Highbridge House, Brixton-hill.
STRUENELL-BRETtingham.—On the 2nd inst., at St. James's Church, Paddington, F. W. Struenell, L.R.C.P., of Highgate road, to Elizabeth Susette, second daughter of the late Richard F. Brettingham, of Carlton-road, Maida-vale.

DEATHS.

AITKEN.—On the 23rd August, of sunstroke, on board the s.s. *Peiho*, one day after leaving Singapore, Ewing M. Aitken, M.R.C.S.E., aged 26.
HUNTER.—On the 7th inst., suddenly, at the Army and Navy Club, London, Thomas Hunter, Esq., M.D., Deputy Inspector-General of Hospitals, late of the 4th (Queen's Own) Hussars.
SMITH.—On the 29th ult., at Stuttgart, Robert Smith, Deputy Inspector-General of Hospitals (retired), aged 72.
SPARKS.—On the 11th inst., at Misterton Lodge, near Crewkerne, the residence of his brother, Edward Isaac Sparks, M.A., B.M. Oxon., F.R.C.P., younger son of William Sparks, Esq., of Crewkerne, aged 37.
TINKER.—On the 2nd inst., suddenly, at her residence, Talbot House, Southport, Mary, relict of the late Frederick Tinker, F.R.C.S.E., of Hyde, Cheshire, aged 63.
WATTS.—On the 8th inst., at Battle, James Watts, M.R.C.S.E., in his 91st year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

SOMETHING NEW.

THIRTY-SEVEN nurses of the Poplar and Stepney Sick Asylum have petitioned for a monthly allowance instead of beer. The petition was not granted on the ground that the plan had been tried in nearly every hospital in London, and not found to work well. It was decided that nurses who did not take beer should be allowed an equivalent in milk, lemonade, or anything from the stores, except spirits.

ANTISEPTIC MIDWIFERY.

To the Editor of THE LANCET.

SIR,—I am surprised to find that Mr. Verdon's article on the above subject, in your issue of Sept. 25th, has remained unnoticed. Mr. Verdon surely is trifling with the common sense of the profession when he publishes such a case as showing the value of Mr. Lister's treatment applied to midwifery. Whether it be possible or not to apply Lister's treatment to midwifery, it is quite clear to anyone familiar with the principles and details of that treatment that Mr. Verdon did not even attempt to surmount the difficulties peculiar to such cases. He does not even allude to how urination was accomplished. Moreover, this woman had a very bad time of it, being four or five days with fever and other symptoms, and barely convalescent on the eleventh day. Mr. Verdon appears to attribute this to the poison of erysipelas, as the nurse was developing an attack of facial erysipelas at the time of the confinement. This may or may not be. At any rate the value of the treatment is not apparent. But Mr. Verdon tells us he has used antiseptics in ordinary midwifery cases, and with marked benefit. Really one would suppose a successful midwifery case was as remarkable as a successful ovariotomy. There is many an old midwife who would feel proud if she knew of the wonders she had been accomplishing all her life, and that, too, without the aid of antiseptics.

Yours faithfully,

Wittersham, Oct. 4th, 1880.

N. W. ALLT, L.K.Q.C.P.I.

CHLORAL AND OPIUM.

To the Editor of THE LANCET.

SIR,—In reference to the risk stated to arise from the combined action of chloral and opium, I have a patient who has been taking both for some months past, and certainly without any injurious effect. During the thirty-three days preceding Sept. 2nd he took daily from thirty to forty-five minims of tincture of opium (eighteen drachms in all), and a sleeping draught of chloral, varying from twenty to forty grains (fourteen drachms and three-quarters in all). From Sept. 2nd to Sept. 12th he had opium pills only—twenty-nine, each containing one grain. From Sept. 12th to Oct. 10th inclusive he has again taken chloral, sixteen drachms in all, and fifty-six more of the one-grain opium pills.

Yours sincerely,

Lewisham, Oct. 11th, 1880.

H. DISMORE, M.R.C.S., &c.

CAYMAN'S OIL IN PHTHISIS.

DR. HEFFENGER, in the *Boston Medical and Surgical Journal*, advocates the use, in consumption, of the oil obtained from the crocodile. He states that in Peru this oil has almost superseded that derived from the liver of the cod, being thought more nourishing and palatable. It is given in tablespoonful doses, after meals, for long periods.

Mr. C. Priestley.—Our space will not allow us to insert another letter from our correspondent. He will allow that we have given not a little to those who share his views.

Inquirer.—Another report will appear, probably, next week.

DOCTORS AND DEATH CERTIFICATES.

To the Editor of THE LANCET.

SIR,—I am much obliged to you for your courtesy and kindness in your notice of the charge of 3s. 6d. for a death certificate in your edition of October 2nd. Family bereavement has detained me from noticing it earlier. The facts of the case are as follows:—The woman called here with her child on Sunday night. I was at home; but my assistant, Mr. Bowden, saw the child, and prescribed for it, saying at the time, "This child is so very ill that possibly it will not live long. You had better be attended at home, and pay 3s. 6d. for the week." The reason of 3s. 6d. charge is that I have a private, a club, and a dispensary practice here, and, on the principle that poor people can only pay moderate prices, we charge for children, 9d., for adults, 1s. each bottle of medicine at the surgery; for a single visit at home in the day, 1s. 6d.; for a week, 3s. 6d. This was the origin of the 3s. 6d. idea. We heard no more of her until Tuesday morning, when she called on me, and asked me for a death certificate, saying her child was dead. I said, "I don't remember your name. Who saw you?" In answer, "Mr. Bowden." "When?" "On Sunday night." I said, "Call to-morrow (Mr. Bowden not being present), and I will inquire all about it." She did so on the Wednesday. I told her, "I have inquired into your case. You are greatly to blame. We visited in the same house on the Monday, and yet your child being so ill, why did you not ask us to attend, or some other medical man?" She replied, "The gentleman said the child would probably not live, and I did not think you could do anything for it." I said, "Do you mean deliberately to ask me for a certificate of death without having seen your child?" The answer was, "Yes, I can pay for one. A friend of mine had one from another medical man." I asked "What medical man?" and she told me his name was "—," and that she paid 1s. for it." I said, "Now if you had paid your 3s. 6d. as was asked of you, your child would have been seen night or day, and then you would have received a certificate in the ordinary way. As it is, you are more guilty than the woman who brought her child here in a dying state from privation, &c., and was tried at the Old Bailey, and if you give me twenty 3s. 6d.'s I will not dream of giving a certificate." She then said, "Because I did not pay the 3s. 6d. you refuse the certificate." I told her, "If you had paid, we should have been held responsible." She then burst into tears, and asked me what she was to do. I said it would be for the coroner to decide; and out of consideration of the feeling she appeared to evince at her neglect, I said I would inform the coroner. I did so, with the result that I heard no more of the case. Not being asked to attend the inquest, and unheard, I had to bear the blame of this charge, and the remarks of the coroner. I send you his letter, which I received before I heard of the public notice.* I may mention that the coroner's remarks in his letter bear upon the fact that previously I had told him that in such cases as this one—and they are common enough here—I did not see why a medical man should inform a police officer, or the coroner's officer, or even the coroner, of a death, as we had no fund to do so with. I may mention that we had seventeen cases of dead bodies we have been called to, and in no one instance has a post-mortem or medical evidence been called. My assistant, Mr. Wm. Bowden, who has been with me for over a year, heard my remarks to this woman, as also another person present.

I remain, Sir, yours truly,

JAS. W. AYRES, L.R.C.P.E., &c.

Union-street, Deptford, Oct. 6th, 1880.

* "Greenwich, S.E., Sept. 24th, 1880.

"DEAR SIR,—In reply to your letter of the 22nd inst., I held an inquest in the case of T. J. Jenkins last evening, and the jury returned a verdict of 'Died from convulsions.' It is not my custom to give certificates as to the cause of death when no inquest is held, neither am I in the habit of taking the individual opinion of a police constable as to the necessity of an inquest.

"With reference to your complaint of there being no fund to repay the medical gentlemen for their trouble in informing the police or the coroner of a suspicious death, I regret I am unable to assist you in this matter, as I possess no authority to recoup any expenses incurred for that purpose.

"I fail to perceive that you would be put to much expense or inconvenience when applied to by a relative of a deceased person for a certificate,—which you do not feel yourself justified in giving,—that they must communicate with the coroner's officer of their parish, or, if you have reason to believe that the relatives have not done so, to draw the attention of the first constable you meet to the matter.

Yours faithfully,

"ED. ARUNDEL CARTTAR.

"Jas. Wm. Ayres, Esq., Union-street, Deptford."

A. G. P. should call on the practitioner in question, and come to a friendly understanding with him as to the case and its future relations. Such questions must constantly arise, and should admit of amicable settlement. Something depends on the degree of intimacy of the parties, and much on the disposition of the patient. We quite perceive that our correspondent puts his questions in a proper spirit towards Mr. D.

Enquirens.—1 and 2. No.—3. The Fellowship of the Royal College of Surgeons of England.

Dr. Spencer.—We regret that the letter is not suitable for our columns.

AN ILLUSTRATION OF THE SYSTEM OF CHEAP DISPENSARIES: A REPLY.

To the Editor of THE LANCET.

SIR,—It would be too bad were such a prejudiced and misleading statement as that of your correspondent "M.D." allowed to pass unchallenged.

First, he endeavours to confuse the issue by throwing upon dispensaries the odium which properly attaches to unqualified and ignorant practice—ill weeds, indeed; but they would still be found flourishing in the keeping of many a prosperous practitioner if every dispensary were closed to-morrow.

Secondly, "M.D." invites the inference, and, indeed, takes it for granted, that the cost of the medicines he ordered—all of which were, of course, absolutely necessary—must have been three shillings, because the chemist charged that sum. I would remind "M.D." that it is not the usual practice at dispensaries to send prescriptions to be made up at a chemist's, that these gentlemen usually make a profit on the drugs they dispense, and that "M.D.'s" calculations would have appeared more ingenious had he estimated the cost at one shilling instead of three.

I will not criticise the somewhat cumbrous artillery which "M.D." brought to bear upon his patient, but will leave it to those of your readers who have had much experience of the disorder referred to to decide, whether such a case would not, as a rule, have been adequately met by a zinc powder and cotton-wool locally; and, if the neuralgia was severe, by a morphia injection, and a mixture containing arsenic, strychnine, and gelseminum, which could have been supplied at a cost of twopence or threepence.

With reference to "this kind of slopwork," which "M.D." properly inveighs against, it is indefensible. But I should like to ask any medical man who has conducted an extensive dispensary practice how many poor patients he has seen in one year suffering from scabies, who have been dosed with repeated bottles of medicine at 2s. 6d. apiece, and nothing else? How many trussed and treated herniæ that cannot "face the light," and similar blunders, not the work of unqualified assistants, but of qualified and flourishing M.D.s, who may perhaps derive satisfaction from the reflection that, whatever their fees, they can never be called cheap.

No doubt there are grave abuses at some dispensaries, so there are in all classes of practice; but that does not justify the indiscriminate statements which have been so freely made, and which are stamped with envy, hatred, malice, and all uncharitableness.

Professional ignorance and carelessness are only too common, but they are not monopolised by dispensaries, and I don't doubt that if all the mistakes committed at dispensaries were collected, they could be matched by cases which come to them from neighbouring practitioners.

Yours faithfully,

October, 1880.

M.R.C.S.

To the Editor of THE LANCET.

SIR,—It may make my illustration of the evil of the cheap dispensary system more complete if I say that since writing my last letter the patient has called to report himself well, and to pay my charge of two guineas, fully convinced, too, I think, that if he did not get all he wanted at a cheap dispensary for a shilling a week, he got all he could reasonably expect. The point of my present additional illustration is that not only is the patient likely to be misled and badly catered for at a cheap dispensary, but the profession is injured by one of its members doing for a shilling a week a service for which, as in this case, the patient can pay, and pay cheerfully, a guinea a week.

Your obedient servant,

London, October, 1880.

M.D.

To the Editor of THE LANCET.

SIR,—I am sorry to say that "dispensary doctors" are not the only ones in our profession who charge unprofessional fees. I am in practice in the country, and in a part where the men make good wages; yet a firm of surgeons here will go from one end of the place to another for 1s. 6d. fee, including visit and medicine. I am also informed that a powder for a child can be had at their surgery for 6d., and that they are not above selling 2d. worth of castor oil. Surely these "surgeons" should add the word "chemist" to the plate on their door!

I remain, Sir, yours truly,

Sept. 28th, 1880.

ANOTHER L.R.C.P. Ed.

THE COLLEGES OF PHYSICIANS AND THE TITLE OF DOCTOR.

M.D.—We entirely agree with our correspondent; but we consider the question closed, and admitting of no further discussion.

Ærom.—We cannot insert the inquiry.

Accoucheur.—The patient should have given notice of her confinement, and our correspondent has a certain legal claim upon her. Whether it is worth pressing in Court, we must leave to him to judge.

Dietetic will find part of his argument against "M.D." used by another correspondent. His views of the use, or rather the uselessness, of drugs are very peculiar.

J. R. should consult a qualified medical practitioner.

INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—Your leader of the 29th May last, on the Imperial Policy of the Government of India in Medico-sanitary Matters, is a truthful, though trenchant, remark upon what prevails in this great English dependency.

As if to mock the recognised opinions of the most eminent authorities in Europe on cholera, its pathology and etiology, the Government of India has just ordered that the returning troops from Cabul should march through Tangi, in Peshawur, where cholera is believed to be raging severely. The telegram from Simla states that "as the Government of India does not countenance the contagion theory, our brave soldiers, after facing all the dangers of war," are once more to experiment with their lives upon a theory which is now an established fact.

In India we have no public opinion, and as regards public medical opinion we are deplorably behind even the early days of the Apothecaries' Society of London. Official etiology and pathology take precedence of everything. Medical education being entrusted to the hands of Government officials, it is easy to understand how religiously they uphold official views, both from the professorial chairs and in medical journals held exclusively by them. No newspaper, and especially no medical journal, would receive attention or support unless placed under official influence. To understand such a deplorable state of affairs in this vast empire, one has only to study the native character. A glance at some of the proceedings of the Calcutta Medical Society will at once show how the official medical autocrats get the support of the hungry aspiring youths of India.

I would draw your attention to the discussion on the "new disease" recently epidemic in Calcutta, which was officially announced as *beri beri*. No idea was more ridiculous or more revolting to educated medical men than such absurdity. Official opinion has been given grudgingly to the views of the profession in Mauritius, where a similar epidemic disease prevailed; but the ill grace which marks the change of front is too apparent in the last issue of the *Indian Medical Gazette*. I will send you a description of the Mauritius epidemic, known as "acute anæmic dropsy," as well as a full report of the epidemic here, as observed by me. In Mauritius the blood of those suffering from the disease was examined in several instances under the microscope, which revealed the presence of spirilla (beaded or chained). My observations showed some of the fission-fungi present in recurrent fever, as well as higher organisations, which I hope to be able to send to the Royal Microscopical Society, with a description. There is little doubt in my mind that relapsing fever and typhus have concurrently prevailed in Calcutta, and that the diseases still continue, but less extensively. It is left to be seen if the next winter will not cause another epidemic. I might state here that the unusually protracted fall of rain in some places, and the absence of it from others, is likely to result in damage to the crops, and scarcity once more. The history of Indian famines and pestilence will soon rival similar phenomena in Ireland.

I remain, Sir, yours truly,

Calcutta, August 25th, 1880.

MEDICUS.

To the Editor of THE LANCET.

SIR,—In your leading article of Oct. 2nd you have pointed out the unfair way the changes in the administrative grade of the Indian Medical Service have been effected, and which appear to have been made for the special benefit of sanitary officers, who have been promoted from the grade of surgeon-major to surgeon-general, over the heads of their seniors, many of whom were selected for promotion to deputy surgeon-general years ago by the same Government which has now ordered their supersession.

There is one grievance which you have omitted to allude to, and which was lately pointed out in your columns by "Bengal Retired"—viz., the postponed allotment of retiring annuities from the Indian Medical Funds to those officers who have been compelled to retire through ill health, and from whose pay large sums have been deducted for twenty-five years, with the understanding that they would receive at the above average period of service a retiring annuity, but of which they will be now deprived for an indefinite period by the large influx of senior officers on the retired list, through the reduction of administrative appointments in the Military Department of the Indian Medical Service, which were formerly obtainable by seniority. As no satisfactory answer on the subject can be obtained from the officials at the India Office, I would suggest that a Fund be raised by retired officers for the purpose of obtaining counsel's opinion as to whether we cannot claim our annuities, in return for the subscriptions which were calculated by an actuary to furnish these annuities, at the average period hitherto prevailing.

Your obedient servant,

East India United Service Club, Oct. 4th, 1880.

MADRAS RETIRED.

Dr. H. R. Walwyn.—Application should be made direct to the Secretary, stating the special circumstances of the case. The general rules do not apply.

Dr. Peters, (Davos).—We regret that we are unable to find space for the communication.

Mr. A. T. Norton.—The MS. has been received.

A QUESTION IN PHARMACY.

To the Editor of THE LANCET.

SIR,—In your issue of October 9th, "L.K.Q.C.P." asks how to prepare a solution of morphia for subcutaneous injection. If he will refer to the last edition (1874) of the British Pharmacopoeia, he will find "injection morphiæ hypodermica," which might answer his purpose. This preparation, however, when long kept, deposits a little of its salt; consequently only a little should be made at once, or the addition of a little glycerine will keep the preparation any length of time. Some practitioners object to this addition of glycerine, as it is said to irritate the skin a little occasionally. When making a strong solution of morphia, it is necessary to use a perfectly fresh salt of morphia. Hence, in making the "injection morphiæ hypodermica," the Pharmacopoeia orders the dissolved hydrochlorate to be precipitated with ammonia, and then redissolved with a little acetic acid, so that a solution of a freshly prepared salt may remain.

Yours truly,

October, 1880.

R. W. W.

To the Editor of THE LANCET.

SIR,—For some time I have used the following solution of morphia, and found it keep well:—Acetate of morphia, twelve grains; carbolic acid, five minims; distilled water, one ounce. Dissolve the morphia by gentle heat, and when cold add the acid, which must be pure. I frequently to the above add five grains of extract of belladonna, which I find prevents sickness. I have never found this deposit the morphia, and it has the advantage, after injecting, of causing no smarting.

Yours &c.,

March, Cambs, Oct. 11th, 1880.

W. EASBY, M.D.

To the Editor of THE LANCET.

SIR,—In answer to the question in pharmacy by "L.K.Q.C.P." in your last issue, I find the following keeps very well:—

R. Morphiæ mur., gr. xxiv.

Atropiæ sulph., gr. ss.

Glycerini, 3ij.

Aquæ, 3vi.

M. v. contains $\frac{1}{2}$ gr. morphia.

Yours &c.,

Dublin, October, 1880.

J. L. B.

MALTA AS A PLACE FOR PRACTICE.

Migrator would like to know if "S. G." in THE LANCET of the 2nd instant asks with a view to going or for curiosity's sake.

A Constant Reader is referred to the article on Books in our Students' Number, Sept. 11th.

Dr. Burney Yeo.—Shortly.

Alpha has forgotten to enclose his card.

TUBERCULAR DEPOSITS IN THE BOWELS AND PERITONEUM.

To the Editor of THE LANCET.

SIR,—Dr. Finlay's case of tubercular peritonitis, reported in THE LANCET of Sept. 25th, reminds me of one of tubercular deposition in the bowels and the peritoneum that I had under my care in May last.

A. L—, aged seventeen, had always been a weakly anæmic girl. Menstruation occurred for the first time twelve months previous to her present illness, recurring at irregular intervals. Latterly she had suffered much from obstinate constipation. She walked almost daily a distance of two miles to her place of business, a woollendrapers' warehouse. Tea formed the principal article of her diet. On Sunday, May 9th, she walked two miles in the country, and on her return home she was taken ill with violent vomiting, coldness of the extremities, and a feeling of soreness (not particularly localised) throughout the abdomen. That night and the following morning the vomiting continued with but slight intermission.

I saw the patient for the first time on Monday at 10 A.M., and, in addition to the above account, learned that she had been menstruating the whole of the previous week, and had walked daily to and from her place of business. Menstruation was now very painful. Vaginal examination revealed the uterus retroverted and tender. The feeling of soreness throughout the abdomen still persisted. Physical examination of the chest showed nothing abnormal. There were no symptoms of cerebral disturbance. Temperature normal; pulse 82. The examination was frequently interrupted with violent retchings. I succeeded in getting the uterus replaced. The bowels were cleared by an injection, and mustard was applied to the epigastrium. She was ordered bicarbonate of potash with hydrocyanic acid, a pessary of belladonna and hyoscyamus, and enemata of brandy and beef-tea. Vomiting occurred at least a dozen times throughout the afternoon and evening, and on the following Tuesday. Creasote, bismuth, bicarbonate of soda, pepsin wine, bromide of potash, and wood-charcoal were tried, some alone, and others in combination.

The only drug that seemed to allay the vomiting was charcoal given in twenty-grain doses. Wednesday and Thursday were passed in comparative ease, and the patient slept well. On Friday vomiting occurred three times, and the temperature fell to 96° in the axilla. On Saturday the vomiting was again excessive, but the temperature had risen to the normal. On Sunday about 5 P.M. she called to her mother for a drink of water, but expired suddenly before receiving it.

In this case the constipation and violent vomiting would have led one to suspect some form of intestinal obstruction; but then at no time were there febrile symptoms, actual pain was never complained of, and the constipation was easily overcome. On the other hand, the symptoms might have been caused by the retroverted uterus, as in Dr. Graily Hewitt's case read before the Clinical Society of London. In A. L—'s case, however, replacement of the womb did not remove her distressing symptoms.

Post-mortem examination of the abdomen only was allowed. On the peritoneal layers I counted eight deposits of grey tubercle, each surrounded by a patch of congestion, the bloodvessels radiating in streaks from the deposits. Nowhere was the patch of congestion as large as a sixpenny piece. Throughout the entire length of the bowel there were found twelve deposits, the bloodvessels in close proximity to the tubercles being very large and distinct. Three perforations were discovered in the duodenum, two being evidently of recent origin. The stomach contained a little fluid and some pieces of toast. The womb was slightly enlarged, both ovaries being of a beautiful violet tint. The remaining viscera were healthy.

Yours truly,

M. D. KELLY, L.R.C.P., L.R.C.S.

Newcastle-on-Tyne, Sept. 30th, 1880.

Medicus.—1. He would certainly be unfit, and we have no doubt he would be considered so.—2. Our article on Books in the Students' Number will answer this question.

Dr. Reimann, (Kiev.)—Thanks.

A very Old Subscriber is thanked for bringing under our notice a very unprofessional bill.

Mr. A. Durand.—We must decline the proposal.

Dr. Sousino, (Cairo.)—We shall be glad to see the paper.

COLOUR-BLINDNESS AND RAILWAY EMPLOYÉS.

To the Editor of THE LANCET.

SIR,—In reference to your annotation of Oct. 2nd, I may say that the English Railway Companies, as well as the Indian, are fully alive to the necessity of strict examination of candidates for their service, and, in strict justice to them, I may say that as long ago as my appointment to the Great Western Railway as surgeon for this district in 1866, one of the questions was, "Can he see well, and distinguish one colour from another?" while the Midland Railway form expressly enjoins that the candidate's sight as to "distance" and "knowledge of colours" shall be specially reported on. The public, therefore, need not fear that so important a matter has been overlooked. But my special object in writing is to say that during the fourteen years I have examined men for these two Companies I have met with so few cases of strongly marked colour-blindness that I think its frequency is overrated. The most marked case I ever saw was a very fine young man, who had been a sailor, and who was utterly unable to distinguish between red and green either in the form of flags or (in a dark cellar) of the two colours in railway lamps, the only concession I could get from him, when he found from my examination that he had "gone wrong," being that he thought one was "a rather lighter green than the other." Cases are of much more frequent occurrence in which there is inability to distinguish different shades of the same colour and gradations of tint; but there is also a comparatively very large number of cases in which the supposed colour-blindness is not this phenomenon at all, but simply colour-ignorance, and it requires considerable care to distinguish between this and the true colour-blindness; for I have often been surprised at the extreme difficulty, especially among the agricultural population, in naming even the primary colours, where experiment showed that practically they thoroughly knew the difference between them, and it seems to me very probable that many of these cases have been classed as colour-blind.

One word as to the mode of examining patients for this affection. I used to have circles painted on a card for candidates to name. On one occasion a man did this very glibly and correctly; but on further testing I found he was the subject of colour-blindness sufficient to disqualify him for railway service, and I had good reason to believe that my card of coloured-discs was too well known, and that the sequence of them had been carefully noted. Since that time I have adopted a rough-and-ready but very effective method. I tell the candidate to go to my book-case, and place his hand upon a red, yellow, green, and blue book, and if he selects these colours readily from among scores of others I am satisfied; but if he chooses obscure tints of the colour for which he is asked, as sometimes happens, I then carry out a much more rigorous application of tests.

I may say, in conclusion, that more evidence is required before we can assume that this curious condition is as prevalent as has been assumed.

Yours obediently,

ROBERT BIGGS, M.R.C.S., L.S.A.,
Surgeon to Great Western and Midland Railways,
Bath District.

October, 1880.

DELIRIUM FROM POISONING BY FUNGI.

To the Editor of THE LANCET.

SIR,—I shall feel greatly obliged if you will allow me to ask your readers for references to cases of delirium from poisoning by fungi.

I am, &c.,

October, 1880.

The above Scale of Charges is arranged upon the basis of the classification adopted in the Index.
NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is itself an additional advertisement.
Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.
Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.
Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or subscriptions should be addressed.
Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.
The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers.
Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.
A First Issue is made each week at seven o'clock on Friday morning, for the Wholesale Houses only.
A large Colonial Edition is also published for despatch the same day.

An Address ON ELEMENTAL PATHOLOGY,

Delivered in the Pathological Section of the British Medical Association,

By SIR JAMES PAGET,
PRESIDENT OF THE SECTION.

(Concluded from p. 607.)

THE resemblances which, in human pathology, we trace between the processes of repair and some of those of Inflammation are well-marked in plants. Of course, in speaking of inflammation in plants, we must be nearly limited to the essential parts of the process. In ourselves, we look to its so-called signs—in heat, redness, pain, swelling, and disturbed function; but these are not of the essence of inflammation, and, even in ourselves, one or more of them may be absent when yet the real process of inflammation is active. For the elemental pathology of inflammation, as for that of decay and of repair of injuries, we must study the altered relations between the elemental formed parts and the varying formless materials about them; and these, let me repeat, may be seen more nearly in plants than in animals, in which it is hardly possible to isolate any parts from the influence of stagnant or wandering corpuscles or of circulating blood and nervous systems.

The signs of inflammation, I have implied, cannot well be observed in plants. Increased heat in the part has not, I think, been noticed; yet I suspect that, with so rapid organisation as sometimes ensues in gall-formations, it might be detected. Redness is often present, as in the galls and curled leaves of which I shall speak presently; but it is in a fallacious likeness to the redness of congestion of blood; it is only the colour of imperfection which one sees in many immature and many decaying leaves. Pain we cannot suppose in plants; and yet it may be through some change like to that of transmission of nerve-force that we must explain what I find told by Frank,¹ that in many green parts of plants there appears, some few minutes after wounding them, a change in the normal position of the chlorophyll-grains and the protoplasm in cells at a distance from the wound—a change which, as he says, must be regarded as due to the transmission of a stimulus of some not well-known kind from the wounded to the intact living cells. Slight slowly-ensuing swelling is often evident in the inflamed parts of plants, and is due, as in animals, to new formation and to increased afflux of nutritive matter—an afflux, be it observed, not due to any vaso-motor nerve-change. Disturbed function is evident enough.

But the likenesses between the inflammations in plants and in animals are best shown in their visible structural changes; and these have been admirably traced by Waldenburg.² He has applied various irritants to leaves, fruits, and stems—such as foreign bodies, setons, crushings, cauteries, and others. The results, speaking very generally, are: that, as in ordinary wounds, the cell-structures actually involved in the injury perish and dry up; that those most nearly adjacent suffer degeneration, indicated by their protoplasmic contents becoming turbid and their chlorophyll becoming yellow or brownish; while in those next to them, and within distances varying according to the injury and the texture of the part injured, enlargement of cells ensues, and increase by division and thickening of the cell-walls.

In these changes you may study, with comparatively easy experiments, imitations (as near as difference of texture will allow) of the most constant constituents of inflammation in animals, especially those of the least acute of the productive interstitial inflammations, leading to thickening, opacity, induration, and other such changes. The defective maintenance of some of the natural structures of the part is evident; so is an increased afflux of nutritive material; so is an increased production of lowly organised structures not widely different from the natural structures.

But of all morbid processes in plants, none, I think, are so suggestive as are those produced by parasites, whether vegetable or animal. The whole subject would be far too large to speak of, even if I were familiar with it; it is, indeed, a subject of the gravest national importance; but, keeping to the design with which I started, and which was only that of pointing-out where useful pathological knowledge may be gained, I will speak of only some of the changes which are produced by insects. The most remarkable of these are the Galls;³ and among the many hundreds of them that have been described I may assume that you know some in their natural mode of growth—such as the common oak-apple, with which some celebrate the restoration of our monarchy, and the bedeguar of the wild rose, the bright-crimson oak-spangle, the currant-gall, or the artichoke-gall, or the gall of pharmacy. But, besides the hundreds of different true galls, there are still more hundreds of changes of structure in leaves and stems and roots, all produced by the irritant secretions of insects, and all such as may justly be ascribed to processes of inflammation. In some, as in the “curl” of the leaves of the whitethorn, you find thickenings of leaves which are lifted, rolled, or curled into chambers which serve for defence of the aphides or other insects; in some, the thickened and distorted clusters of leaves, in buds or twigs, roll-up and are mutually fastened so as to form the walls of similar defensive lodgings; in some cases, leaves become swollen as with a kind of oedema; in some, their layers separate as if with blistering; or leaves, or stems, or fruits, or clusters of flowers, buds, or roots produce variously shaped and variously constructed growths of cellular parenchymatous tissue and cork, and, more sparingly, of woody tissue or of cells, whose thick walls become as hard as wood. Besides, some of the monstrous growths of parts of plants, and some of the viviparous variations, and the undue metamorphoses of leaves, are to be referred to the influence of parasites.⁴

It may seem bold to speak of so many hundreds of widely various morbid processes as having any essential character in common, or as fit to be included under one name; yet, I think, we may regard the whole of these as being such as, in our pathology, we should call inflammatory hypertrophies or hyperplasias. They all show a rapid increase of lowly organised structures, by derivation from, and in continuity with, those pre-existing. There is, as in the products of our inflammations, a general likeness among these new structures whatever be the part of the plant from which they are derived, and all bear a general likeness to the structures formed after injuries of actively growing parts. In the morbid growths formed by these new structures, the deflection from the natural shape and construction of the part, in continuity with which they have grown, is often not complete; they often retain marks of characteristic normal forms, and sometimes acquire marks of natural variation from the species.⁵ Moreover, all these morbid growths have their origin in what may justly be called “irritation” of the part on which they grow; and in all of them, I think, we may note signs of degeneracy from natural conditions, either in the absence of stomata or similar structures, or in the presence of the red, or yellow, or other colours commonly noticed in decay.

Here, I believe, are reasons enough for regarding all these galls and gall-like products of disease, generated in plants by insects, as analogous with a large group of the products of inflammation which we study in our own

³ Many growths like galls are produced by fungi and other parasitic plants; but those I omit. Many are described by Schroeter (Beiträge zur Biologie der Pflanzen, Band I., p. 4) and by Beijerinck. The best essays on the minute structures and modes of growth of galls are those of Lacaze-Duthiers in the *Ann. des Sciences Naturelles, Botanique*, 1853; of Prillieux, in the same; *Botanique*, 1876; and of Beijerinck, *Bijdrage tot de Morphologie der Plantegallen* (Utrecht, 1877). But I am most indebted to Miss E. A. Ormerod, who, by her admirable works on Entomology and Meteorology, sustains the scientific reputation of the name so well known to pathologists. Since the Address was sent to press I have received the second part of Frank's essay in the *Encyclopædie der Naturwissenschaften*, containing a much fuller account of galls and gall-like growths than, I think, had before been published. With this, or with the soon-coming second part of his separate *Pflanzen-pathologie*, and with Beijerinck's essay, the whole subject may well be studied by any human pathologist. But I hope that it will soon be yet more clearly illustrated by Dr. Arthur Ransome.

⁴ Among them are the “witch-brooms” of the birch, pine, larch, &c. Miss Ormerod has described the “Phytophys of the Birch-knots” in the *Entomologist*, 1877. A long list of the teratological forms due to parasites is in Beijerinck, *loc. cit.*, p. 32. With this should be studied Dr. M. Masters's volume on *Vegetable Teratology*.

⁵ As Darwin pointed out in the likeness of the mossy covering of the common wild-rose-gall to the calyx of the moss-rose. There are, also, instances in which galls imitate small cones or other structures of the plant.

¹ *Encyclopædie der Naturwissenschaften*, Abth. i., Lief 12, p. 333, from a paper by him in *Pringsheim's Jahrb. f. Wiss., Bot.* viii. p. 220.

² *Virchow's Archiv*, Band 27, 1863, p. 145.

pathology; and the analogy is not the less because neither group can be circumscribed with any exact definition.

I will not be tempted to speak long, but I beg you to think long, of the marvellous facts of natural adjustment which we have here, in this intense example of the "*sic vos, non vobis*." Here are the bare facts. Each species of these parasitic insects can compel some part of a plant into such disease as shall supply good food, or well-built and well-placed lodging, or both, for itself or for its eggs and larvæ, or even for part of the life of its complete offspring. Each insect selects, by instinct, the very part of the plant which is adapted to its purpose. The provision made at the cost of the plant is exactly adapted in quality to the welfare of the insect or its offspring, and in quantity as well; for both the lodging and the food are made sufficient for any necessary time—for days or weeks, often for many months; in some instances, for two or even three years. Nay, more than this, the gall, of which the growth has been provoked by the virus of one insect, may be fit for the food and lodging of another, which, when all seems complete, can penetrate the gall-cavity, and there, as with theft or murder, obtain food and lodging perfectly suited to itself or its progeny.⁶ And the whole process in the plant, though it be one of disease and, in a sense, unnatural, is yet so regular, so constant and specific, that the form and other characters of each gall or other morbid product are, usually, as constant and characteristic as are those of the insect itself, and the differences among the galls are at least as great as those among the insects. Is there, in all the range of natural history, a more marvellous group of facts than may here be studied? If you would like to work out a problem in evolution, find how it has come to be a part of the ordinary economy of nature that a gall-insect compels some part of a plant to grow in a manner which, while injurious to the plant, becomes useful to one insect not yet born, and to another who will, in due time, kill this one and feed on it.

But now, of the relation between galls and our specific diseases, such as our eruptive fevers, syphilis, cancer, gout, and others.

In these galls and other similar diseases in plants we have, it seems, hundreds of specific diseases due to as many hundreds of specific morbid poisons;⁷ for the most reasonable, if not the only reasonable, theory of these diseases is, that each insect infects or inoculates the leaf or other structure of the chosen plant with a poison peculiar to itself. The poison may be merely deposited; but, in the instances best for study, it is inserted in the plant-structure, whether leaf or any other; and the wound for inserting it, the poisoned wound, may be made either with part of the oral apparatus, or, as in most of the true galls, with the ovi-positor through which one or more eggs are passed with the virus, and are left among actively living structures of the plant. The little wound closes; the virus, whether an oral or an ovarian secretion, remains, and the result of its influence on the plant-structures and their contained protoplasm is the formation of the gall or other morbid product. The whole process may be compared with the local consequences of the insertion of vaccine-lymph, or any such morbid poison, in ourselves or other animals. I say the local consequences, for we have no clear evidence of what might be called general infection or constitutional disease in the plants. In the absence of quickly moving fluid, such as lymph or blood, the virus infects only the part in or very near to which it is inserted. A single oak-leaf may have fifty "spangle" galls on its under surface, but the structures between them may be quite healthy; and when in any instance a general damage is done to a plant by gall-growths, it seems to be only as a remote consequence of the spoiling of considerable portions of its structures. And this appears to be true, even though the virus may continue active for a long time, as in the galls which begin to grow soon after the insertion of the virus with the ovum, and continue to increase during the whole—sometimes long—development of the larvæ; or even, in a few instances, after the larvæ have deserted them.

But, while plants supply no occasions for studying fever, or any other of the constitutional phenomena of specific diseases, they are all the more fit for illustrations of some of the local

characteristics. Let me suggest some things for study in them, in addition to the inflammatory changes of structure.

We find hundreds of different forms of galls, and we may be nearly sure that there are as many kinds of morbid poisons produced by the gall-insects, each form answering to a different virus. This may suggest that we may be too grudging in thinking of the number of morbid poisons, or of their modifications in the blood, to which diseases in ourselves may, at least in part, be due.

It is true that the galls are produced by many species of insects on many species of plants; and that the differences among these species may be as wide as those between ourselves and any other mammalia. But, even among closely allied species, there are many and very different forms of galls. Mayr,⁸ ten years ago, described and figured ninety-six kinds of galls found on the oaks of middle Europe, all but two of them being produced by different species of gall-wasps. Of those ninety-six kinds, thirty-two are formed on the leaves alone; and, even on similar parts of one oak-leaf, it is not rare to find three or four different forms of galls.⁹

We have, thus, clear evidence of a very large number of morbid poisons, each of which is capable of producing, in an appropriate subject, a distinct specific disease with a characteristic morbid structure.

We may safely believe that, for each of these morbid poisons, there is no test yet possible except that of the disease which it may produce; and so we may as safely believe that there may be many morbid poisons or morbid conditions of blood in ourselves which may be indicated by very different products of disease, though they may be beyond detection by any other, even the most refined, method of research.

Further, though it may be impossible by any other means to detect any differences among these morbid poisons, yet the diseases which they severally produce may be widely different; as unlike as are a pustule and a goitre, or a vaccine vesicle and a carbuncle, or as any of the morbid changes due to gout or rheumatism.

It may be observed, however, that these great differences are marked in outer shape and construction much more than in minute structure. As, in human pathology, there are certain general characters and degrees of likeness in all inflammatory products, however differently they may be constructed—in pustules, vesicles, thickenings, opacities, adhesions, scars, fibroid, and other changes; so, in galls, there are certain likenesses in minute structures, even among those that are, in their construction, size, and outer shape, most unlike.

It may be well to learn from this a lesson on the imperfection of our methods of minute research. As we cannot doubt that the differences in outer shape and method of construction of the products of specific diseases are associated with differences of chemical composition and ultimately minute structure, so it must be in those yet greater differences on which we frame our distinctions of species in all living nature. The coarse, visible, and tangible distinctions may be well marked; the really material differences with which these are associated, and to which, probably, they are due, are beyond our reach.

Again, in the study of specific diseases in ourselves, we see many variations due to the differences in the parts, or even in the persons affected with them. In the study of galls similar variations may be seen. As a general rule, each gall-insect lays its eggs in one part of one plant, as the leaf, leaf-stalk, bud, fruit, or root of this or that species; but if, as rarely happens, one lays in different parts of the same plant, there is usually a very close agreement in the characters of the resultant galls. A few exceptions to this rule are known, one of them being in the very different galls produced on the roots and on the leaves of vines by *Phylloxera vastatrix*; but the rule is generally observed, and accords with the fact of certain features of general likeness being observed in the products of our several specific diseases, wherever they may be seated.

When the same insect lays in similar parts of different plants the galls may be all similar,¹⁰ but I believe they more usually are different, and that their differences are such as bring them severally nearer to the distinctive characters of the plants on which they grow; just as, in ourselves, a

⁶ The Inquilline, Einmiether, lodgers, or (as they might be called) burglars, are usually described in the works on gall-insects, though not themselves "gall-makers."

⁷ Karsch (abstract in the Botanische Jahresbericht, 1879, p. 156) gives the total number of the forms of galls at present known as about 1250, of which one-fifth belong to the Cynipida.

⁸ Die mitteleuropäischen Eichengallen, 1870.

⁹ While writing, I have before me some oak-leaves from a sapling on which are five kinds of galls, three being, in several instances, on one leaf.

¹⁰ Fr. Löw. Ueber Gallmücken. in Verh. der K. K. Zool.-botan. Gesellschaft in Wien, 1877.

specific disease may be modified by the personal conditions of each patient.

In similar analogy the differences are yet greater when the eggs are laid in different parts of different plants.

Very rarely the same insect may produce on one leaf different forms of galls.¹¹

In all these points you may, I think, find help in the study of specific diseases. I will add only one more. Usually the gall begins to grow directly after the deposit of the egg; but sometimes there is a long delay, a long period of suspense, an "Eiruhe,"¹² which may last for many months before the growth begins. What is going on during this time? I believe we may see here an instance of events very difficult to study in our own pathology, in which two or more conditions must concur to the production of some disease, and one of them must wait for the complete efficiency of the rest. In the case of these long-delayed galls, either the egg, after being laid, requires a long time for the completion of changes ending in the production of the necessary morbid poison, or the plant-structure in which it is laid requires the time for changes to make it susceptible of the poison; or both egg and plant may need to change. So in us, two or more conditions must concur. A tendency to gout may be inherited, and the blood may have slowly acquired the necessary morbid condition; but no structure may be susceptible of gouty disease till a blow, or a strain, or some disturbance of nervous force makes it so. So with cancer, a general tendency may be inherited, but it must wait till the material of some structure is by age, or injury, or long-continued "irritation," changed into fitness for concurrence in morbid action with the material on which the general tendency depends. Then, when the two materials meet in mutual fitness, the result may be a change so great, that we may compare it with that from an act of impregnation. I have often thought of this comparison when seeing the almost sudden appearance of cancer in a breast or a tongue or a scar long irritated. In the growth of these galls the comparison may seem less far-fetched; at least, it may be difficult to suggest any nearer comparison for a process in which the meeting of two living materials from different organisms is immediately followed by such a change in the method of life of one of them, as ends in the production of a definite new growth exactly adapted to the method and purpose of the life of the other.

But it is more than time that I should have done with galls. If I have been tedious, let me assure you that I am myself ashamed to have gathered so little from the rapidly increasing records concerning them to which the botanists, and still more the entomologists, of our time are contributing. And, even for that little, I feel as if I deserved to be compared with one of those burglars that I spoke of, feeding on the results of others' labours. Let it be my apology to them, that I believe I have taken nothing they would have used. I have only taken, from their rich stores of facts, some that may be much more useful in pathology than in natural history. And I am sure, from all I know of naturalists, that they will gladly let any of you into their fields, though you may use them for your own purposes much more than theirs. It would be difficult to find a field for the study of the very principles of pathology larger or richer than this offers to you. The objects are within easy reach; hundreds of morbid processes are at hand for deliberate study; experiments may be made at will; and, during many months, thousands of insects, as natural vivisectioners, will be at work for you; and it must yet be some years before they will be required to take out licences.

I will speak of only one more of the subjects of general pathology—that of tumours; and on this I may be very brief.¹³

¹¹ Beijerinck, loc. cit., p. 21, from whom, also, the two preceding sentences are quoted. He cites from Winnertz the case of *Cecidomyia tremula*, which may produce on the same leaf of the white poplar four different forms of galls; but I would suspect that there may be as many differences among the eggs, just as there are among those of some Lepidoptera, in which, out of the same brood of eggs, all laid in the same place, some are hatched in the next following season, others in one, others in two, seasons later. Of course these eggs are not all alike, though no other difference besides that proved by the times of hatching may be discoverable in them, or in the insects produced from them.

¹² Schenck, Beiträge zur Kenntniss der Nassauischen Cynipiden, p. 24. He cites the case of *Trigonaspis megaptera*, which lays its eggs in May, and the galls do not appear till the next April; others lay in buds, and the galls appear at the time of opening of the leaves. Hartig mentions similar facts (Zeitschr. für die Entomologie, Band ii., p. 176, 1840).

¹³ What is here said of morbid growths, and some of the deductions from the study of galls, were, for the want of time, omitted in delivering the address.

I do not know if there be any morbid growths in plants which may justly be compared with our cysts or cystic tumours. Foreign bodies lodged in them usually give rise to such changes in the immediately surrounding textures as produce layers of cork-tissue, which may be compared with the capsules of connective tissue similarly formed around foreign bodies in animal structures,¹⁴ but I do not know if there be any such diseases as cysts filled and enlarging by the increase of secretions or growths from their own walls.

Growths which may be coarsely—and only coarsely—compared with our cheloids are common on elms and other trees, especially on apple-trees. They are called cankers, or in Germany by the same name as cancers—Krebs.¹⁵ They are usually rounded and coarsely nodular masses of wood, covered with bark, sessile singly or in clusters on branches, and depressed at the middle of their projecting surfaces. Thus, in form, they are not far unlike masses of scirrhus cancer projecting from the breast or axillary glands; and the likeness is the nearer when, as is usual, the depression on their surface leads into a cavity bounded by decaying wood. The imitation of an ulcerating cancer may justify the use of the same name; but in the canker of the trees the central cavity usually indicates the beginning, not the advance, of the disease; for cankers, like most cheloids, are formed after wounds—whether from frost, or blow, or injury of parasite, or any other cause. Around these wounds layers and bosses of wood are annually heaped up, as if with an exaggeration of the process of repair, and with concentric growth they may close in and complete the likeness to the cheloid. But more commonly, while the outer part of the canker is annually increasing, its inner part is constantly decaying under the attacks of the parasites which the wound let in, and which plants seem to have no power to expel. Thus, within a kind of shell of laminated wood, outstanding like a tumour on the branch, you may find a great hollow space filled with rotten wood and other residues. It may look very like a mass of cancer, with central softening and decay; and the likeness is even greater when, as not rarely happens, the central decay keeps pace with the formation of new wood. Then is formed what some call an open cancer; others gangrene or Brand. In these an uneven surface of rotting and dead wood is surrounded by an undulating, knotted, and everted or overhanging border of the wood annually formed, but in its turn destined to decay, and thus to imitate the constantly enlarging cancerous ulcer with its nodular uplifted borders.

It is impossible not to be struck by these likenesses between cankers and cancers, and I commend them to your study, though I fear they are much more apparent than real. The nearer, yet still distant, likeness seems to be that to cheloid growths; for these also appear as morbid troubled processes for repair, and they are so far like to tumours that no line of definition between them seems yet clear.

The growths in plants which may, I think, be deemed most nearly like to our tumours, are those which are called exostoses,¹⁶ knours, or wens. They may, indeed, be regarded as only prominent examples of that disorderly growth of adventitious buds which produce the various strange and beautiful knots and veins in ornamental woods; but they are too like tumours for me to pass them by. You may find plenty of them on the trunks of the beech, hornbeam, ash, birch, holly, and cedar. The best specimens appear as ovate or nearly spherical masses of hard wood partly covered with bark, which is reflected on them from the continuous bark of the trunk on which they rest. They range from a few lines to many inches in diameter, and are attached sometimes broadly, sometimes by short narrow pedicles continuous with the wood of the tree. Some are without pedicles, and lie as free encapsuled masses in the growing wood.

In many of these conditions there is a very strong resemblance between these growths and some of the bony exostoses after which they are named. Especially when one breaks them off the trunk of the beech, or the holly, or cedar, and sees their pedicle of attachment and the bark-like integument and periosteum, continued over them, one cannot but compare them with the narrow-based ivory exostoses of the skull or the pedicled exostoses which are common on the

¹⁴ See Arlring in Ann. des Sc. Nat., 1874, t. iv. p. 27.

¹⁵ Sorauer, Handb. der Pflanzenkrankheiten, 1874, p. 199, &c.; Göthe, Ueber den Krebs der Apfelbäume; Leipzig, 1877.

¹⁶ Berkeley in Gardener's Chronicle, 1855 and 1857; Trécul des Loupes et des Broussins in Ann. des Sc. Nat., t. xx., 1853. An excellent account of the knots and veins of wood to which they are related is given by Frank; loc. cit., Maserbildung, p. 394.

femur and humerus, or with the sessile fibroid uterine tumours.

On section, they show themselves formed of very hard wood; and their pedicles appear as cylinders of wood passing from their centres into continuity with the normal wood of the trunk. Through these pedicles, while they last, the exostoses probably obtain some of their materials for growth; when detached, they wholly subsist and increase on materials derived from the cambium spread out over them. In this continued growth, when encapsuled, they resemble the typical tumours of our pathology more than do any other morbid growths on plants; and they may continue to grow so long as nutritive material is supplied to them.

Now, the history of these growths is very suggestive to us. They are derived from buds, which remain, as Trécul says, in a sort of lethargic state for several years, and then become active, and form either a little branch or a *loupe* or exostosis, which, in its increase, will project more and more beneath the bark. Surely, they may thus confirm that theory of tumours which regards those whose structure does not differ widely from the natural structures as growths derived from portions of germinal substance remaining, though one knows not why, for years "lethargic," and then becoming active, growing in their own method, and subsisting on materials derived from the living parts around them.¹⁷

Before I end, let me briefly say some things in apology and self-defence.

If I have seemed to speak as a botanist or any kind of naturalist, I have erred. It is more than forty years since I was a botanist, and anyone familiar with the science as it now is may justly say that I know nothing about it. He may detect at once my ignorance even of the language in which I have tried to tell where, in the field of botany, good facts for pathologists may be found.

I have not tried to deal with the whole subject of the diseases of plants. It is far wider than I could learn, even if the duty of my life were not to study those of men. I have not tried to learn more from them than may help to give me, and perhaps you, a clearer and wider view of human pathology and the duties it imposes upon us.

In dealing with even this narrow range of the diseases of plants, and in referring to the vastly greater number of those which occur in them—especially in the plants which we, to our own not their advantage, cultivate—I may seem to have been giving evidence against belief in the influence of nervous systems in the production and methods of organic diseases. I have had no such design against any reasonable belief of the kind; I have long held, and often declared, belief in the trophic influence of nerve-force. An alteration in the nervous force in a part can surely alter its method of nutrition, even without altering the condition of its blood-vessels, as much as an alteration of its temperature can; and, to cite no others, the facts which Brown-Séquard and Hutchinson brought before us yesterday, tested as they have been, are beyond refutation. Only, let us learn from a pathology more nearly elemental than that which we can study in ourselves, that many processes of disease, even the most various, may occur when there is no nervous system; and that there are many processes of degeneracy, and of repair, and of disease, of which the essential features are alike whether in the presence or in the absence of a nervous system. The study of such processes in plants, and even in crystals, may help us towards learning the real relation between the nervous force and the processes of organic disease. A certain normal condition of nervous force abiding in each part accessible to it may be deemed a necessary condition of the healthy life of that part; as a certain normal temperature is a necessary condition, and perhaps even a certain electric state. But we are bound to recognise the distinctions between the conditions of life and the essential properties of living things; and, as I proposed when beginning, so now, I hope I may have succeeded in showing that it will be very useful if you will study pathology in bodies less complex than our own, especially in such as are not subject to those conditions of our own elemental organic life, which are of all the most difficult to estimate—the conditions, namely, of a nervous system and a quickly circulating and quickly changing blood.

And now let me, only for a minute, claim the position of a senior in our profession, that I may tell how the study may

be useful for something more than the direct advancement of knowledge.

I hold it to be very desirable that every one of us should, all his life long, study some science in a scientific manner. There seems to be no equally good method for maintaining the temper and the habits which, by making us always good students, will make us as good practitioners as we can be. There is no method so good for maintaining a constant habit of inquiry, with accuracy and perseverance in research, the power of weighing evidence, of calmly judging, and of accurately speaking; none better for cultivating the love of truth, the contempt for fallacies, whether others' or our own, the gentleness and courtesy which are appropriate to the consciousness of the imperfection of our knowledge.

You may say that we can study science in the practice of our profession. So we may; at least, some of those among us may, who, before getting into practice, spent many years in scientific pursuits, and acquired habits which it is very hard to lose; but, even for these, the study of science in their practice is too much like that which, I suppose, an astronomer may pursue in some stormy night on a railway journey. For really scientific study, we need repeated observations in unchanged conditions, the right to watch deliberately the course of natural events, sometimes to change that course when and how we please, to set down our descriptions of the objects of our study, even while we watch them, sometimes to have them at home and readily at hand for revision and refreshment of memory. These and many other conditions for scientific study cannot be had in our practice, in which our first and never-ceasing duty must be to do, as soon as we can, all the good we can, though in doing it we may lose or spoil all the best opportunities of acquiring fresh knowledge.

If, then, I am thus far right, that we all are always bound to study a science in a scientific manner, and that it is very hard to do this in our practice, let me again commend to you this elemental pathology. In any fragment of it, studied in those fragments of time which we are all too apt to waste, you may find ample opportunities for observation and experiment, for recording, collecting, and comparing facts, for generalising, for imagining and testing; thus you may gain the happiness and reputation of discovery; and, without ever leaving the paths of duty, you may refresh and strengthen your minds in the study of stores of beauty, wonder and utility, such as, in all ages, have attracted the wisest and the best of men.

DIPHTHERIA AT ST. GEORGE'S HOSPITAL.

By T. WHIPHAM, M.B.,
PHYSICIAN TO THE HOSPITAL.

CASE I. — Esther S. C., aged six, was admitted under Dr. Barclay's care into St. George's Hospital on April 21st, 1880. The parents and relatives were healthy. The family originally consisted of ten, of whom five died of "coughs and teething" between the ages of one and two. One died soon after birth, and one died on the day previous to the admission of this child from "disease of the throat," with which it had been attacked on April 19th. The patient had "measles and bronchitis" a few months ago, otherwise had been healthy. On April 19th she was attacked with sore-throat and hard swelling below the angle of the jaw on each side, having been previously free from throat affection. The swelling rapidly increased, and was accompanied by difficulty of swallowing, cough, restlessness, loss of strength, and great thirst.

At the child's home there were at the time of her admission two other children apparently in good health. No similar throat affections had been heard of in the neighbourhood of their dwelling (King-street, Chelsea). There was, so far as the mother was aware, no defect in the drains, and the house was free from bad smells.

The patient was of strumous aspect, with fair hair and delicate skin, but well nourished. There was much swelling beneath the angles of the lower jaw; the swelling was of about the size of an egg, and hard; and from the nostrils

¹⁷ I think that many examples of "club" on the roots and stems of cabbage and other species and varieties of the same order may illustrate the growth of tumours. But some are certainly insect-galls, and the parasitic origin of others is suspected.

came a glairy discharge. There was neither cough nor dyspnoea. The tongue was clean, but the soft palate and pillars of the fauces were covered with a thick white membrane. Pulse 125, fairly strong, and regular. Temperature in the evening 100° F.; respiration 30. Deglutition difficult.

April 22nd.—Slept fairly well; no delirium; took fluid nourishment without much difficulty; some, however, returned through the nose; bowels confined; pulse 160, weak, regular; temperature 99° in the morning; no urine passed. The patient died at 9 P.M. from sudden failure of strength; there was no obvious dyspnoea before death.

The treatment consisted of ten minims of tincture of the perchloride of iron, and two minims of dilute nitro-hydrochloric acid in two drachms of water every two hours; ten ounces of port wine daily, strong beef-tea and milk, of each two pints.

At the post-mortem examination no membrane was found, but the mucous membrane of the fauces, larynx, and trachea was intensely congested, and covered with a little thin, purulent secretion. The heart was contracted, and to all appearance natural.

CASE 2.—Alice C—, aged twelve, sister to the above, was admitted under Dr. Barclay, on April 21st, 1880. She had always been healthy, and at the time of her admission was well nourished. She had had measles a few months ago, but had not been subject to throat affections. This child was suddenly taken ill about midday on April 21st, and she complained of pain under the lower jaw, and of difficulty in swallowing.

When admitted she was very prostrate; the neck was much swollen; there was swelling below the angles of the lower jaw, and the child spoke with difficulty. She was admitted in the evening, a few hours after her sister. She resembled her sister in appearance—i.e., she had light hair and fair complexion, and was well nourished. There was slight dyspnoea, but no cough or expectoration. There was much difficulty in opening the mouth; a whitish membrane was visible on the soft palate and tonsils. Temperature in the evening 103°.

April 22nd.—Passed a restless night, with some delirium, but took wine, milk, and egg-and-brandy mixture; respiration was somewhat noisy; no action of the bowels; pulse 140, weak but regular. Temperature: morning, 104°; evening, 103°; urine highly albuminous.

23rd.—Almost pulseless; restless and delirious at night. Took but little nourishment. Died of asthenia in the evening.

Treatment:—Twelve ounces of port wine, four ounces of brandy mixture, with two pints of strong beef-tea and milk. No post-mortem examination was made.

CASE 3.—Annie B—, aged twenty, general servant, was admitted under my own care on April 19th, 1880, in an extreme state of depression, suffering from pneumonia of the back of the left lung. It appeared from the history that the patient was in her usual health on April 13th. On the morning of the 14th she was unable to get up, and when her parents saw her on the 17th she was delirious. The delirium continued, being worse at night, and on the 18th she became so violent that two persons were required to keep her in bed. There had been diarrhoea for a day or two before her admission. She had been comparatively free from cough. She was ordered two pints of strong beef-tea and milk, five ounces of port wine and an egg.

April 20th.—She was delirious at night; one loose motion had been passed in the bed; no urine had been passed, the bladder was therefore emptied with the catheter, and the urine was found to be clear, acid, sp. gr. 1015, albuminous.

At the time of my visit her face was dusky; she was much depressed, delirious, but when roused answered questions rationally. She was constantly picking at the bed-clothes. Her skin was hot and dry; her tongue moist (probably from fluid nourishment, which she took readily). Pulse running and weak; respiration quick and shallow.

A hurried examination, which was all that could be attempted under the circumstances, revealed pneumonia of the lower lobe of the left lung posteriorly. The abdomen was flaccid and free from spots. She was ordered quinine and nitro-hydrochloric acid, and in the evening four ounces of brandy. A poultice was applied to the chest.

21st.—Owing to the indefatigable exertions of the head nurse, the patient was wonderfully improved in every respect, and was partially sensible. About noon one of the children, Esther S. C—, was brought into the ward, and placed in a bed nearly opposite to her, and remained there

for two hours and a half, when she was removed to the separation ward.

22nd.—The patient passed a very restless night; slept about twenty minutes only, and was very delirious. The urine and faeces were passed unconsciously in the bed. Respiration 42, chiefly abdominal, with marked movements of the alae nasi. Tongue thickly coated, dry and brown. She took both brandy and nourishment well.

23rd.—Passed a better night, but otherwise showed no improvement. She occasionally complained during the day of sore-throat. This was attributed to the fact that the brandy had been administered with as little water as possible, in order to save her the fatigue consequent upon the exertion of swallowing. She took nourishment and stimulants readily.

24th.—Passed a restless night, with low muttering delirium; still she continued to take food, almost with avidity. At 9 A.M. she spat up a tenacious white membrane, which had the appearance of having been moulded to the form of the soft palate and fauces. On examining the mouth at 1 P.M. I found the soft palate and tonsils and pillars of the fauces covered with an opaque, white diphtheritic membrane. A spray, consisting of lactic acid, five minims to an ounce of water, was ordered to be applied to the throat frequently, and the parts covered by the membrane were brushed freely with a solution of benzoate of soda (two drachms to six ounces). The brandy was increased to eight ounces. During the early part of the night the delirium was somewhat less, but there was more difficulty in swallowing. She died exhausted at 4.30 A.M. on April 25th.

The body was examined fifty-eight hours after death. Decomposition was already very far advanced, and was far more evident than in the case of another body in which life had been extinct twenty-four hours and three-quarters longer. Externally the neck was swollen, the skin much discoloured, the superficial veins clearly marked, and the subcutaneous tissues infiltrated with blood-stained serum. The thyroid gland was much enlarged. The mucous membrane of the fauces, larynx, trachea, and larger bronchi was intensely congested, but no distinct membrane was found: the mucous surface of these parts being merely studded with minute yellow points, apparently the remains of the diphtheritic membrane. The back of each lung was greatly congested, and the tissue of the left soft, and easily broken down by pressure: portions of the left lung, on being thrown into water, sank at first, and then slowly rose to the surface. The organs of the body generally were much decomposed and blood-stained; the heart, though contracted, was flabby;

the blood fluid. The liver was soft, and especially greasy in appearance.

CASE 4.—Probationer S—, aged thirty-three, had been on duty for some weeks in the male accident ward, and on the evening of April 21st was told off to take charge of the two children, Esther and Alice C—, in the separation ward, having been up to that time in her usual good health.

On April 23rd, at 5.50 P.M., the second of the children died, and in the course of the evening Probationer S— complained of sore-throat.

Next day at 1.0 P.M. I saw her: she was looking pale and anxious, with a weak pulse of 110. She complained of feeling very ill. Her right tonsil was much swollen and very red: on its inner surface was a ragged-looking yellow patch of about the size of a threepenny-piece. The patch resembled the sloughy condition of mucous membrane such as is commonly observed in cases of "hospital sore-throat." She was ordered a mixture containing tincture of perchloride of iron twenty minims, chlorate of potash one scruple, dilute hydrochloric acid twenty minims, sulphate of quinine two grains, spirit of chloroform half a drachm, water one ounce, every four hours, with eight ounces of port wine. She was also directed to take as much strong beef-tea and milk as possible, and to spray the throat frequently with a solution of lactic acid (five minims to one ounce.)

On Sunday, April 25th, Mr. E. V. Dickinson, who was officiating as house-physician, sent me a notice that the patient was much worse. At 8.15 P.M. I saw her, and by the indifferent light of a candle I found the soft palate and tonsils much swollen; the parts being, as far as could be seen, oedematous. It was impossible to be certain as to the presence of a membrane. There was great swelling of the neck, and especially of the parts below the angles of the lower jaw. The lactic acid spray was continued, and the throat was ordered to be swabbed out with solution of benzoate of soda (two drachms to six ounces) at frequent intervals, and spongio-piline saturated with warm Goulard and laudanum applied to the neck. The wine was increased to sixteen ounces, and eight ounces of egg and brandy mixture prescribed.

At midday, April 26th, I learnt that she had taken both food and stimulant readily; had passed a sleepless night, having suffered much pain in the throat, but had had no delirium. The neck was very much swollen, and the fauces and tonsils were covered by a dense white membrane.

The same night, between midnight and 1 A.M., I saw her again, when some slight improvement appeared to have taken place. The pulse was 120, and was a trifle stronger. She still continued to take all that was given her, but the pain in swallowing was very distressing. She was free from cough, but constantly hawked in order to remove the mucus from the throat. As far as could be seen by the candlelight the membrane had cleared off the pillars of the fauces. The inability to open the mouth wide, however, prevented accurate examination. The tongue was sore, swollen, and coated with a thick, dirty-white fur. The bowels acted freely. She was perfectly conscious, and still continued to take the wine, brandy mixture, and fluid nourishment. At 4.30 A.M. she became much worse. Mr. H. Griffiths, the house-physician, saw her, sprayed the throat with lactic acid, and applied the benzoate of soda freely. Both afforded relief in that they alleviated the dryness of the throat and the pain on swallowing. About 5 A.M. Mr. Griffiths again saw her, as she was evidently sinking, and again sprayed the throat for nearly an hour. Her pulse at this time was 160, and extremely weak. She took wine and nourishment in less quantity, owing to the painful deglutition. At 6 A.M. she died from asthenia, having been free from delirium and quite conscious to the last.

This patient was from the first very despondent, and expressed doubts as to the probability of her recovery. Shortly before her death she remarked to the nurse in attendance on her, "The Princess Alice kissed her children when they were ill, and I kissed the children downstairs." She was menstruating during her illness. Some urine, however, was drawn with a catheter for examination, but was unfortunately thrown away.

(To be concluded.)

MR. SAMUEL STRETTON, M.R.C.S.E., has been placed on the Commission of the Peace for the Borough of Kidderminster.

EXCISION OF ONE LATERAL HALF OF THE TONGUE.

PRESENT CONDITION OF THE FIRST PATIENT,
OPERATED ON IN 1865.

By GEORGE BUCHANAN,

PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF GLASGOW.

IN the *Edinburgh Medical Journal* for November, 1865, I described an operation for removal of one lateral half of the tongue affected with epithelial cancer, which I had contemplated for some time, but first put into practice in the case of Mrs. M—, from Arran, on Aug. 12th, 1865. The proceedings consisted of dividing the lower lip in the centre; sawing through the lower jaw at the symphysis (as formerly done by Mr. Syme in his operation for removal of the whole tongue); separating the tongue and sublingual apparatus from the floor of the mouth; drawing out the tongue by two loops of strong thread passed through each side of the tip; cleaving the tongue in the centre, from the tip to the epiglottis; and then dividing the attachments to the hyoid bone with a probe-pointed knife.

The principle thus introduced, of removing only the affected lateral half by cleavage, has been variously modified by using the *écraseur* or thermo-cautere to divide the attachment to the hyoid bone, with the view of obviating the necessity of tying the lingual artery; but the surgeon has more certainty as to what he is cutting away, when he uses a sharp probe-pointed knife; and I have never seen any difficulty in tying the lingual artery in the stump, when the remaining half of the tongue is well pulled out. Also, on more than one occasion, I have seen it necessary to ligature the artery after the divided half of the tongue had been removed by the *écraseur*, and it was much more difficult to catch the mouth of the vessel in the crushed stump left by the *écraseur* than on the clean surface left by the knife. I incline therefore to return to the operation as I first performed it.

The only objection to this proceeding is what is applicable to all cases of epithelial cancer—viz., the possibility of the disease reappearing in the glands below the jaw or in the neck. But if the operation is undertaken before there is any affection of the lymphatic glands, and if the excision is effected wide of the diseased parts, then the relief, which in my experience is at all events uniformly temporary, is in many instances permanent.

The object of this short communication is to state, that this autumn Mrs. M—, the subject of my first operation, called on me to report that now, fifteen years after its performance, she remains in perfect health, with no annoyance from the loss of half of her tongue. She can speak quite intelligibly, though of course there is a little defect; and she can swallow quite well.

The tongue is rolled over on the cut side (as is the case usually after this operation), so that when it lies in the mouth, or is projected, it is narrow and pointed, like the tongue of a bird. There is not a trace of thickening, hardness, or pain.

A NOTE ON INTENTION IN THE DETERMINATION OF SEX, AND THE MENTAL AND PHYSICAL INHERITANCE, OF CHILDREN.

By J. MORTIMER GRANVILLE, M.D.

THE laws determining the sex and the physical and psychological inheritance of children are not as well formulated as they ought to be, and the influence of intention, working under and through these laws, is therefore practically *nil*. It is scarcely creditable to science that this should be the case, considering the vast array of facts with which we are surrounded, all pointing to the conclusion that a better and fuller acquaintance with these laws would tend to the improvement of the human race, and the abatement of disease. Nor is the reduction of the laws of procreation and transmission to practice a Utopian project, inasmuch as their broad principles admit of application by individual pairs; and, subject necessarily

to the disturbing effect of collateral influences, they will produce the results which science enables the student of the principles of sex and heredity to predicate. It would be impossible within the limits of a short paper to give the evidence upon which the following conclusions have been reached, nor is it my purpose to attempt an argumentative proof of the propositions to be presently stated. A simple summary of facts observed independently, and now for the first time, so far as I am aware, brought together and submitted for consideration in their natural relationship, is all I contemplate. The inferences suggested certainly require, and they admit of, proof, but it must be left to time to work that out. I shall content myself with stating two propositions as briefly as the conditions of clearness will allow.

1. It has been shown by direct experiment with the lower animals, and is known to the most expert breeders of stock, that sex is determined by the relative aridity of the two parents. A preponderance of impulse on the part of the male parent produces female offspring, while excess on the part of the female parent produces male progeny. Facts commonly observed in relation to the human species show that the same law governs the determination of sex in man. Among these may be mentioned the following:—(a) The first children of quickly married parents are generally females. This is particularly noteworthy in the case of men marrying with a strong feeling of personal affection, or an especial desire for heirs. (b) Children born as the result of unions in which the female parent is not a consenting party, or is averse from the union, are almost invariably females. (c) Female children commonly resemble their male parents in early life, and at the successive periods of change occurring in the course of development and decadence. On the other hand, the offspring of unions, or periods, in which the female parent is the more ardent are nearly always males. (a) The first children of parents whose union has been long delayed are generally males; so also are those of unions in which the male parent is not specially attached to the female. (b) The offspring of unions in which the desire of the male parent for an heir has become less ardent, while that of the female parent has increased, are generally males. This is a very common experience, whose significance has been strangely overlooked. (c) Children born under circumstances in which the female parent is the more exigent are, with rare exceptions, male. Large families of boys indicate the existence of a constitutional excess of the procreative force on the part of the female parent, or a relative deficiency on the part of the male; while a family consisting of girls is proof of preponderance of the same quality in the case of the male parent. When an odd child of the opposite sex is born in the midst of a one-sided family, it is generally weakly, or in the proportional development of its mental and physical systems exhibits the weakness of the force which has exceptionally produced it. Children born late in the life of the dominant parent are frequently characterised by disproportionate development of the mental and nervous, or the more strictly *animal*, parts of the being. Of course, every rule has its exceptions, but the exceptions to these rules are very few. It commonly happens that instances which seem to transgress the general law of sex-determination are found on close inquiry to conform to it strictly. I believe that law to be one of the most universally kept, with the fewest exceptions, among the known orders of occurrence—which we call laws—of life and development. Granted the conditions necessary to establish a predominance of the procreative force on one side of the parentage, the offspring will be found of the opposite sex. Thus arises the question of “intention.” Assuming that the conditions essential to a proposed result can be established, the event will almost certainly follow the measures taken for its production. This is the first conclusion to which the facts observed obviously point. Sooner or later science will recognise the significance of the lesson they teach.

2. The inheritance of mental and physical qualities, so far as the emotional temperament, the nerve-state, and the less permanent characteristics, are concerned, follows the line of the force that determines the sex; while the deeper constituent elements of the “nature,” elaborated by family influences, pass directly from father to son, from mother to daughter. The new organic result—i.e., the offspring of the union, with its consequential and dependent properties,—will be determined by the law that makes all effective power the resultant of the combined forces of which it is composed. The inheritance will not therefore be simply the qualities of body and mind received from the dominant parent,

plus what the less ardent parent contributes, but will be the mean of the two sets of qualities, in such state of combination as may be determined by the mental concord or sympathy of the parents, and the compatibility of their organic constitutions. With qualities of mind and properties of the organism—so far as these two series of phenomena may be separable even in thought or for the purposes of argument—are transmitted mental and physical defects, weaknesses, irregularities of faculty or form, and consequent abnormal proclivities; the several forms of disease and derangement descending in the same line with the constituent elements to which they are most closely related. Thus, peculiarities of temper, nerve-state, and habit, with their morbid tendencies generally, follow the oblique line from father to daughter; while the underlying elements and characteristics, both good and evil, pass directly from father to son, from mother to daughter, subject to the laws of development, to which we will advert presently.

The study in detail of the laws governing heredity has been too much neglected. Had it been pursued with greater care and industry we should not have heard of many strange terms that have crept into use even in technical phraseology. For example, “atavism” does not clearly or adequately express the fact it is employed to denote. The *seeming* absence of certain elements of the hereditary constitution in one generation and their re-appearance in the next or a later generation, is not a mere accident, but precisely what we should expect under the operation of the natural laws governing sex and heredity. Thus a father may transmit certain peculiarities to his daughter, and she will pass them on to her son, who consequently inherits from his maternal grandfather. The female link in the chain being incapacitated by her sex for the development of certain parts of the *entailed* inheritance, they lie dormant in her organism, to be transmitted, like vitalised but ungerminated seeds, to her offspring when she becomes a parent. That is understood, but that which is not so generally recognised is that this latency is not the simple consequence of incapacity on the part of the daughter to develop the inheritance in her own person, because of her sex; but the result of the repressive operation of other forces inherited by her directly from her mother. There are, in fact, two lines of inheritance—the direct and the oblique. To the former we owe the perpetuation of the likeness of body and mind observed in families bearing a particular name. The force acting in this line is the stronger, or, perhaps, I ought to say the deeper laid and more persistent of the two. This is proved by the preservation of characteristics in the direct descent. The oblique line tends to the dispersion of the inheritance through the daughters of a house and their male children. To make this clear, suppose the existence of two families which we will call respectively *A* and *B*. A male of the house *A* marries a female of the house *B*, and two children are born, a male *A B* and a female *B A*. A male of some other house, say *C*, marries *B A*, and has a child, *B A C*, who inherits the peculiarities of *A* transmitted through *B A*, thus dispersing the inheritance of the house *A* through the house *C*; but *A B*, the brother of *B A*, besides inheriting the surface characteristics of the house of *B*, obliquely through his mother, receives the deeper underlying qualities of the house of *A* directly from his father, so that the constitutional characteristics of the family *A* are handed down from father to son and preserved in the direct line with the name. If the energy of transmission were not stronger in the direct line of inheritance, with the descent, than in the oblique, it is easy to see that family characteristics could not descend intact, as is the fact in society. The direct force is superior to the oblique, though the introduction of powerful female elements into the line of descent may do much to weaken it. What we call “atavism” is due to the circumstance that in the case of a male child, although the energy of the female parent determines the sex and does much to influence the surface type of the organism, the force of the male parent preserves the constitutional type. This enables the male characteristics to reassert themselves in any generation in which the female influence, though sufficient for the determination of sex, is not so strong as to influence the whole course of development. Therefore the latency of peculiarities of constitution is not rhythmical, but irregular, the force directly transmitted generally, however, regaining its ascendancy in every second or third generation. The term “atavism” is not so much erroneous or inapplicable as inadequate. It does not explain or even define that which it designates. The laws of inheritance are inseparable from the

laws of development, which may be summarised as follows: 1. There is a force operating to produce an animal of the class *Homo*, in obedience to the law of the development of species. 2. There is another force gravitating upon this, the outcome of geographical, climatic, and racial energies and influences, which tends to give the animal so produced a national type. 3. There is a force, of which we have been speaking—namely, the energy of family exclusiveness. 4. There is the individual entity, which embodies the sum of the ancestral energies so far as these have been transmitted or may be revived.

Intention in relation to heredity is the purposive employment, interruption, or control of the laws known to us, for the production of a given result—such as the extinction of disease or deformity, and the engrafting of a healthy stock. It cannot be doubted that science has a wide, and as yet unworked, field of enterprise in this department, from which the richest and best fruits may hereafter be gathered. It lies within the scope of the medical profession to attempt the cultivation of this field, but before good work can be accomplished the subject must be investigated and the province thoroughly explored. One of the first and most suggestive considerations in connexion with the practical aspects of this subject is that it is by repression as well as desuetude the evil parts of an inheritance are to be destroyed. It seldom happens that a morbid or evil element in the entailed estate of nature can be directly eliminated, but it may be starved and crippled and finally destroyed by repression and exhaustion. We can only eradicate special disease by the cultivation of special health. It is not enough to keep an inherited defect or evil tendency in abeyance, some healthful quality or property of the nature should be encouraged to over-lie and restrain it. Some sturdy branch must be trained across it. Diseases and morbid tendencies do not die out by virtue of neglect alone. They are only to be destroyed by the cultivation of other characteristics of organic form or function; of "nature" or "habit"—to use vague terms loosely—which have antagonistic or incompatible tendencies. It is not commonly within the power of the physician to make or mar the unions to which affection or policy impels adults; but it is strictly within his province and duty to offer advice that shall help to mitigate the evils, and enhance the advantages, of such unions as have been contracted. And the family medical adviser can generally find opportunity to direct a course of training—physical, mental, and moral—for children which will tend to the fostering of any inherited, though latent, forces that may be capable of being used to repress or repair the defective traits of the young organism. We leave too much to chance in relation to the propagation of the species and the improvement of the race. "Intention" has a part to play in the determination of sex, and in the revival or repression of inherited forces, by an intelligent use of the laws of Nature, which is not yet even recognised.

Welbeck-street.

CASE OF TRAUMATIC TETANUS.

By JAMES MORE, M.D.

ALTHOUGH the following case had a fatal termination, it is, I think, a good illustration of the therapeutic value of chloral hydrate in cases of traumatic tetanus. The attack was one of extreme severity, and, clinically speaking, had three distinct stages, each having characteristic features of its own, marking alike the progress of the malady and the effect of the remedies.

A. B—, a strong, healthy-looking coachman, forty-three years of age, had his middle finger crushed in a chaff-cutter. Adhering too rigidly to conservative surgery, tissues were unfortunately left in the first dressing, which sloughed, exposing and ultimately necrosing the bone to the middle joint of the finger. This may or may not have had anything to do with the occurrence of tetanus; but nevertheless decided symptoms of this dire malady set in just ten days after the accident.

His symptoms and appearance correspond precisely with the classical description of the most acute form of traumatic tetanus; for he had pleurothotonos, opisthotonos, well-marked risus sardonius, clenching of the jaws and grinding of the teeth, difficulty in breathing, in speech, and deglutition, high temperature, quick pulse, and profuse sweating.

These symptoms lasted, with little or no intermission, for twelve days, rising quickly to a pitch of intensity, with almost continuous pleurothotonos, and then again gradually subsiding to a state nearly free from tetany, and characterised chiefly by extreme weakness, moist skin, a pulse 120, full, soft, and compressible, and a mean temperature of 100°. During the intensity of his attack, his body seemed fixed in a curve, his disabled hand pressed against the wall to prevent himself, as he told me, being forced out of bed. The risus sardonius, which up to the ninth or tenth day after attack, and before chloralism was established, had been most marked, was gone. He now slept well, could swallow easily, and felt free from the terrible sternal tetanic pain.

This improvement in all the more urgent symptoms was not, however, quite decided till Nov. 23rd—i.e., the nineteenth day of attack. Before this date was reached the tetanic paroxysms, though not occurring as it were rhythmically or continuously, were still easily induced. Thus, being sick one morning he vomited, and this brought on intense spasm in the laryngeal muscles, so that for an hour his attendants thought he would have died. Again, during one of my early visits I witnessed one of these induced attacks. In drinking some wine-and-water rather hurriedly a fit of choking came on, with clenching of the jaws and grinding of the teeth, his mouth being filled almost at once with viscid mucus. On his brother attempting to raise his head his body arched from occiput to heels, so much that I could easily have passed a pillow under him from one side of the bed to the other. He was then bathed in perspiration, and his pulse was hard, full, and varied from 120 to 130. The treatment up to this time had been thirty grains of chloral hydrate every four hours, a morphia and belladonna suppository at bedtime, and the bowels kept open by giving each night an enema of turpentine and castor oil.

On the nineteenth day decided improvement set in. His face looked placid and cheerful, the tetanic paroxysms had now almost left him, his pulse had lost its extremely high-tension character, being only 98, and though full was fairly compressible. His skin was moist, and the temperature 98°. Thinking his recovery assured, and keeping in view the fact that tetanus kills not so much by the lethal grasp of its paroxysms as by the fatigue and exhaustion induced by the force of the muscular movements, I reduced to a considerable extent the dose of chloral, and this the more as I dreaded its weakening effect upon the already exhausted heart. That this was premature may be imagined, when I record the fact that no sooner had my poor patient got from under the relaxing influence of the chloral than all his symptoms returned, and that with even greater force and intensity (I had almost said malignancy) than before. This recurrence of the tetanic symptoms was in part, as above indicated, due to the too precipitate withdrawal of the chloral, but the immediate cause, I believe, was due to intense bronchial irritation. The weather at this stage of his illness was, perhaps, colder than any we have had for some years. Snow was on the ground, and some nights twenty-seven degrees of frost were registered. There was no fireplace in his bedroom, nor, indeed, upstairs, and though I had a stove fitted up the cold was so intense that even his nurses had to have bottles of hot water to their feet to keep them from shivering. What wonder, then, that, with a moist perspiring skin, dilated arterioles, involving extreme heat-loss, this apparently trivial bronchial disturbance should run quickly into an intense and acute attack of capillary bronchitis.

About the twenty-first day my patient began to have fits of coughing, each fit, to my chagrin, being accompanied and followed by tetanic paroxysms in the laryngeal and respiratory muscles. These tetanic symptoms were quite decided, though still induced, not spontaneous, as at first, but like the necessary discharge of accumulated reflex irritation. When not coughing he seemed calm and free from tetanic spasm, and after expectorating the now muco-purulent phlegm, he seemed, though exhausted, fairly comfortable. To meet this dangerous array of symptoms I felt constrained, in spite of the pulmonary mischief, to return to the chloral, and that in increased doses. I now gave sixty grains of chloral twice in the day, and with it twenty grains of bromide of potassium and fifteen drops of tincture of digitalis. In the bromide I hoped to find a remedy which, with the chloral, would tend to soothe the inflammatory mucous membrane, as well as the tetanic irritation of the laryngeal and respiratory muscles, whilst the digitalis I hoped might

act as a slight cardiac stimulant; for surely this was needed, not only on account of the exhaustion arising from the paroxysms themselves, but on account of the possible weakness resulting to the heart from the large doses of the chloral.

By the twenty-second day the chloral mixture had again improved the general condition of this complicated case. He slept quietly most of the previous night, though on Nov. 26th he had one bad attack of opisthotonos, during which his bowels were forcibly moved in bed. The tetanic tension in the abdominal muscles must during this attack have been very great, for, besides the fact of the fæces being forcibly extruded into the bed, he passed wind with a loud, prolonged, sonorous sound, different from anything I have ever heard. The first night he was under the increased doses of chloral he seemed on awaking to be quite delirious, but this, though furious, soon passed off and did not again return. I suppose this symptom cannot be credited to the chloral alone, but it and the high tetanic tension in the arterioles of the brain carried the state of the cerebral anemia a little too far.

Twenty-fourth day (Nov. 28th).—Since last report my patient has slept fairly well. His pulse (120) was very full, weak, and at times thrilling under the finger. From this date the force of the tetanic paroxysm seemed completely broken. Temperature still under 100°. He had no return of the choking fits, but there was a decided increase in the bronchial mischief. The breathing was shallow and râles were heard in the upper as well as the lower parts of the chest. Cold still intense.

Twenty-fifth day.—A comfortable night, having had four hours and a half continuous sleep. At this date stimulants began to flush him. During the tetanic period he remained under all circumstances unusually pallid. There was evidently now extreme dilatation of the cutaneous arterioles, either the result of the bromide and chloral or the removal of the tension-factors, for the paroxysms had entirely left him.

Twenty-seventh day.—Bronchial irritation worse. To-day his chest was choked up with viscid phlegm, again tending, though in a different direction, to suffocation. Pulse 120, and thrilling under the finger. Breathing 40, face much flushed, the tint being partially cyanotic. For some days he has taken no chloral, but a mixture of ammonia, bromide of potassium, bark, and senega.

Thirtieth day.—General condition of chest not improved. Breathing shallow (50), pulse 100, and to-day, for the first time, showing indications of halting. At times the purplish tint on the face passes into a dusky grey. Temperature 100°; still able to take plenty of nourishment.

Thirty-first day.—My patient died; just forty-one days since receipt of the injury to his finger, and thirty-one since the onset of tetanus.

Such are the facts of this distressing case. Nothing succeeds like success; yet, in spite of its fatal termination, I claim for this case that it is an illustration of the value of chloral hydrate in tetanus. But for the intensely cold and frosty weather, my patient in all probability would have recovered. The first series of tetanic symptoms were undoubtedly controlled by the chloral, and so were the second, though not in such a marked degree, for it might be urged that these tetanic symptoms, purely reflex in character, had, like other reflex irritations, simply worn themselves out. In chloral, with its recognised power of relaxing muscular spasm and abolishing reflex action, we have, as it seems to me, the remedy for all forms of tetanus; but it should be given at once and in large doses, and certainly not withdrawn till all reflex tendency has subsided.

Rothwell, Northamptonshire.

A CASE OF SYPHILITIC ENLARGED SPLEEN IN A CHILD.

By W. J. TYSON, M.B., F.R.C.S.

THE following case is interesting as illustrating how a very large spleen under treatment may become imperceptible, the patient remaining perfectly well, and also as showing that at times the syphilitic poison seems to concentrate itself in one organ, and there exhausts itself. The family history is a profusely specific one, leaving little doubt as to the cause of the splenic enlargement.

The mother, now thirty-nine years of age, has been married nineteen years, during which time she has had thirteen children, and is expecting another next month. The third, fourth, and ninth were still-born; the fifth at ten years old became stone-deaf, and is so now; he had interstitial keratitis. At the present time there are remains of an old iritis; the incisor teeth are notched, and the molars of both jaws are rimmed. The thirteenth had soon after birth a well-marked buttock-rash.

The mother I saw in July, 1875, suffering from a breaking-down gumma of the soft palate, and also perforation of the septum nasi. Since this she has had at various times localised headaches in the region of the temples, coming on always in the evening, generally about seven; this pain being always relieved markedly by mercurial preparations.

The eleventh child, a boy, the subject of this paper, one of twins, was born in May, 1875. Soon after its birth the mother states that the abdomen was enlarged, but he was not seen by me until May 26th, 1877, then two years old. He was pasty-looking. The spleen extended in a downward direction for three and a half inches, reaching the crest of the ilium; in front it approached closely to the umbilicus. The liver was not enlarged. No albumen present in the urine. He was ordered mercury with chalk, one grain every morning and evening; and one grain of iodide of potassium with ten minims of syrup of iodide of iron to an ounce of water, three times a day. On Aug. 1st the spleen was decidedly smaller, and on Oct. 20th it was only one inch below the margin of the ribs. There are no more notes of the case until Sept. 16th, 1878; at this date the spleen was imperceptible and the child in excellent health. The above medicine was taken, as far as I can remember, more or less regularly for about a twelve-month.

Remarks.—I believe that there have been very few cases recorded of large syphilitic spleens in children becoming imperceptible, the child remaining well. I have seen the child this day (Aug. 24th, 1880), and he is perfectly well and free from all visible or palpable syphilitic changes. As these cases improve under the ordinary syphilitic remedies, one would naturally suppose the change in the spleen to be of a specific character, but so far this has not been proved to be so. The change is not an amyloid one. In Dr. Gee's two post-mortem cases, the enlargement seemed to be a simple hypertrophy, and in one there was some thickening of the capsule.

Folkestone.

CASE OF

PERFORATION OF MEMBRANA TYMPANI FROM ASCARIS LUMBRICOIDES.

By LEWIS W. REYNOLDS, M.R.C.S. ENG.

ON March 3rd I was called to see a woman, aged thirty-five, three or four months advanced in pregnancy. She was in a low nervous state, and had been suffering since Christmas from nausea and vomiting. About two weeks before she had vomited several round worms, and about the same time suffered severely from dyspnoea and intense pain in the chest and abdomen. Shortly before my arrival she had vomited two, and three more were discharged from the nostrils, her nose bleeding first for three hours. I prescribed four grains of santonine powder, to be taken at bedtime; after taking which four worms were passed per rectum, for the first time. The santonine was followed next morning by fifteen grains of compound scammony powder, when a great many more were passed per rectum. Three or four hours after taking the second powder, and having previously suffered all night from intense earache, a neighbour discovered a worm protruding from each ear and both ears bleeding; the same day three others came away from the ears, two from the left and one from the right. The following morning, March 5th, her husband drew another from the ear, and again on March 8th; this last was four inches long with the diameter of a small goosequill. A large number were also discharged, each day by the bowel, making in all seventy-four.

On March 10th, and again on March 13th, my patient vomited a large quantity of dark blood, and complained at the same time of a feeling of tenderness in the abdomen, for which I gave demulcents.

On March 17th, in the evening, I was called to see her,

and found her perfectly insensible, having been so since mid-day; her temperature was below normal, but with a fairly good pulse; she was roused again about midnight. The attack appeared to me hysterical. From this time she has gradually improved in health, but has had occasional attacks of diarrhoea.

May 12th.—For the last few days blood has trickled from her ears and down her throat, which she coughs up. On examination with the auriscope, there is now, as there was in March, excoriation of either meatus and a large perforation of both membrana tympani, but the sense of hearing is very little impaired.

Remarks.—The history of this case appears at first almost incredible; but there can be no doubt the membranes were perforated by the passage of the ascarides. In addition to being vomited, some must have crawled up the œsophagus into the fauces, thence some found their way into the nasal passages, and others into the Eustachian tubes, perforating the tympanic membranes and being discharged by the external auditory meatus.

UNIVERSITY COLLEGE HOSPITAL.

[THROAT DEPARTMENT.]

CASES OF PARALYSIS OF THE LEFT VOCAL CORD.

(Under the care of Dr. POORE.)

THREE cases of this form of paralysis have lately been under observation, and since the cause of the paralysis was probably different in each case they form an interesting group.

The first patient, a man aged forty-eight, a cabman, complaining of hoarseness and occasional attacks of dyspnoea, was sent into the surgical wards under the care of Mr. Heath because a laryngoscopic examination made elsewhere had led to the diagnosis of a polypoid growth in the larynx. Mr. Heath sent the patient to the throat department for examination, and it was then at once determined that no growth existed, but that the left vocal cord was completely paralysed. The erroneous diagnosis of growth had probably arisen from the appearance presented by the oblique distortion of the glottic aperture which is so common in these cases, and from the fact that the left cord was almost completely hidden by the left ventricular band, which was somewhat swollen. Laryngoscopic examination produced on two or three occasions violent attacks of dyspnoea. The cause of the paralysis was not at first very obvious. The neck presented no abnormality. The chest was well formed, and without any abnormal prominence. The expansion of the left side of the thorax when compared with the right was slightly deficient, and on very careful percussion an exceedingly trifling deficiency in resonance was detected in the second left interspace, close to the sternal border. On auscultation no abnormal heart sound or bruit was audible, but the respiratory murmur was somewhat weaker on the left side than the right, and on applying the stethoscope in the second left interspace a slight pulsation was communicated to the head of the auscultator, which pulsation was scarcely appreciable to ordinary palpation. Taking all the symptoms together it was considered highly probable that an aneurism existed in the third part of the arch of the aorta, which by its pressure upon the left recurrent laryngeal nerve produced the paralysis of the left cord, and by its pressure upon the left bronchus caused the slight deficiency in respiratory power on the left side. He was admitted into the medical wards, and after rest in bed his attacks of dyspnoea became less urgent, but the paralysis of the cord remained unaltered. When he left the hospital and returned to his work his dyspnoea returned, and the symptoms of aneurism,

which were most obscure at first, became well developed and undoubted.

Remarks.—This case is of much interest, as showing the great value of the laryngoscope in the early diagnosis of aneurism and other thoracic tumours, since without its use to stimulate the physician to a very careful examination of the chest, the slight and doubtful symptoms of aneurism which at first were present would in all probability have escaped detection.

The second case was that of a horsekeeper, aged fifty, who came to the hospital suffering from hoarseness and some difficulty in breathing, and general weakness. A laryngoscopic examination showed a well-marked paralysis of the left vocal cord. There were no indications whatever of the presence of aneurism or other thoracic tumour. The larynx, however, appeared somewhat prominent, and there seemed to be some undue solidity and bulk about the neck, although no distinct tumour was anywhere observable. A few weeks after his first visit he came to the hospital with a piece of meat stuck in the upper part of his gullet, which was removed by the house-surgeon, and a similar accident happened to him a few weeks later. A further examination showed that there was no paralysis of the larynx; and on trying to pass an œsophagus bougie with great gentleness into the stomach, an obstruction was encountered not far below the upper extremity of the gullet. It was highly probable that the obstruction of the œsophagus and the pressure on the recurrent laryngeal nerves which caused the paralysis of his left cord, were due to the same cause. Whether this was malignant or not was never clearly made out, as the patient disappeared when the hospital was closed for repairs.

The third case was that of a shoemaker, aged sixty-four, who was sent to the throat department on October 15th, 1879, from one of the other departments of the hospital, suffering from almost complete aphonia and great shortness of breath. On examining the larynx the fact of complete paralysis of the left cord and slight laryngeal catarrh was fully established. On examining the chest, the left side was seen to be smaller than the right and almost motionless during respiration. There were the ordinary signs of pleuritic effusion rising to the level of the second rib in front, third rib in axilla, and the spine of the scapula behind. Above the level of absolute dulness in front the resonance was defective, especially towards the left sternal border. The right lung presented all the signs of emphysema, and the general form of thorax was of an emphysematous type, with a large antero-posterior diameter. The superficial arteries were everywhere tortuous and pulsated visibly, the right carotid appearing to pulsate rather more forcibly than the others. The heart-sounds were normal, the radial pulses were equal, and there were no indications whatever of thoracic aneurism or other tumour. The history of the onset of the illness was that of acute pleurisy, the patient stating that he had been taken suddenly ill about three months previously with a stitch in the side and sternum. Failing to discover any other cause for the paralysis of the left cord present in this patient, it seems warrantable to conclude that the thickening of the left pleura has implicated the recurrent laryngeal nerve at its origin, a condition which is enumerated by Niemeyer among the causes of paralysis of this nerve.

Temporary immobility of the left vocal cord was present in a middle-aged woman who was suffering from moderately severe laryngeal catarrh, with a good deal of mucous exudation. On first examining the larynx the left cord was seen to be completely immovable, and a diagnosis of paralysis was hastily made, but during a violent attack of coughing the cord, which was apparently mechanically fixed by tenacious mucus, freed itself, and was then seen to move with perfect freedom. This patient completely recovered.

NEWARK HOSPITAL.

OPIMUM POISONING; RECOVERY.

FOR the following notes we are indebted to Mr. J. D. T. Reckitt, house-surgeon.

Ann B—, aged forty-nine, carried on a truck to the hospital by two policemen and her husband, was admitted at 6.30 P.M., Feb. 11th, 1879, perfectly comatose, with stertorous breathing, and a pale, ghastly countenance. The pupils were contracted to a very minute point, and the conjunctivæ were insensible to touch. The breath smelt strongly of spirit, but not of opium. She was totally unable

to stand; in fact, there was complete muscular relaxation, with an extremely feeble pulse. When admitted an hour and a half had elapsed since drinking some laudanum. The husband stated that she had been drinking more or less for some weeks, and was habitually intemperate, gin being her favourite beverage. She often suffered from toothache and pain in the leg. To-day she had applied some laudanum to her leg, and had been drinking gin freely. She was supposed to have taken nearly an ounce of laudanum, purchased of the druggist. She was not an habitual opium eater.

The stomach-pump was immediately applied, and a pint or so of warm water injected. This somewhat roused her and excited vomiting of stained fluid, but without the smell of opium. Strong solution of ammonia was held to the nostrils, which had a decided impression, and after a time, and by means of loud shouting, she was induced to swallow a mustard emetic, which immediately caused free vomiting. Half an hour after this the pulse had improved in tone. Half a pint of the strongest coffee was then given, which, however, she did not retain long. One hour after admission she had still a very strong desire to sleep. The application of the wet towel to face and chest, and ammonia to the nostrils was therefore freely practised; and two hours after admission she was taken into the open air and promenaded by two attendants. The woman was very noisy, and inclined to resist, saying she wished to sleep, but the efforts to keep her awake were steadily persevered with until 2 A.M., when a full dose of compound spirit of ammonia was given, and she was taken to lie down for an hour. The pupils were nearly natural at 3 A.M., though she was then very sleepy. She was indulged with an occasional walk in the ward until 7 A.M., when she ate a fair breakfast, and at 12 o'clock she was discharged, being escorted to the police-station by two policemen.

Remarks.—From the appearance of the patient on admission, the assistant-surgeon, Mr. Smith, who was present during the first part of the treatment, concurred in an unfavourable prognosis; but happily the patient was fairly roused at the commencement, and kept so by the passive motion, until the state of the pupils indicated safety. Thus the ordinary treatment was enough to overcome what appeared dangerous poisonous effects.

KASHMIR MISSION HOSPITAL.

DISLOCATIONS OF THE HIP-JOINT.

(Under the care of Mr. E. DOWNES.)

FIVE cases of this accident have been treated within a comparatively short time. Two were recent cases, and both into the obturator foramen. In these two cases there was lengthening and eversion. Both were reduced at once by manipulation—viz., by flexing the thigh on the abdomen and rotating inwards, and adduction.

The other three were on the dorsum ilii, and were all three old cases.

One was of three months' standing, and though reduced under chloroform easily, and at the time most satisfactorily, the case did not turn out well. The man was old, weak, and infirm; and after the splint had been applied about a week he complained very much of pain, and suffered from diarrhoea—in fact, it was thought that he might die. The splint was taken off at his urgent request, and he unwisely and contrary to expressed entreaties, insisted on flexing the limb. The consequence was that after awhile the limb could hardly be straightened, and was found to be decidedly shortened, and there was great thickening near and above the trochanter. The man became so weak that his life was despaired of, but he finally so far recovered that after some two or three months, when he left the hospital, he used to walk about with the aid of a crutch. The thickening about the trochanter remained, but the pain disappeared; the leg and thigh were somewhat flexed and could only be straightened with difficulty, but there was no inversion or eversion; there was, however, about two inches of shortening. As far as could be made out, the head of the femur was in the acetabulum.

The other two cases are the more interesting ones, and were much alike. The first was seen in December, 1878. The patient was a young man about twenty, strong, healthy, and fairly muscular. The femur was dislocated on to the

dorsum ilii; the position of the limb, with the foot pointing across the instep of the other foot, left no room for doubt. He said that it had been in that position for about six months, and there seemed to be no reason for doubting this statement, for he said that the accident had occurred from a fall from a mulberry-tree which he had climbed for the sake of the fruit and the mulberry season is from the beginning of June to the middle of July. The first inclination was to leave the limb alone, but the young man begged that something should be done. He was placed under chloroform, and the thigh was forcibly flexed on the abdomen, and then brought down and abducted, and rolled outwards. After one or two attempts, a crack was heard and felt, as if the neck of the femur had been broken, but the limb came down to its natural position, with the head in the acetabulum. There was free motion and no crepitation. There was very little shortening; the limb was put up with a long splint. The patient afterwards complained very little of pain, and the splint was worn for a fortnight. At the end of this time the splint was removed, and there was not much shortening. After a few days he complained of some pains on pressure in the position of the head of the femur. Day by day a thickening in that region became more and more apparent, and the limb became shorter. The splint was re-applied, but without effect, and at last it was left off. After the patient had been in hospital a month he went home. There was then no pain to speak of; the thickening was decided, not only over the head of the femur, but in the position from which it had been reduced. There was distinct shortening of the limb of about an inch, but there was good motion at the joint, and no inversion or eversion of the limb. Notwithstanding the shortening he had a useful limb, and walked well with a stick.

The third case was very similar. The patient was admitted in December, 1879. Like the previous patient, he too had fallen from a mulberry-tree about six months before, and the head of the femur had been dislocated on to the dorsum ilii. He was a lad of about fifteen. He crawled into the out-patient room with the dislocated limb shortened nearly three inches, and the femur pointing across the sound thigh at some height above the knee. He was placed under chloroform, and the dislocation was reduced even more easily than in the former case; no crack was heard when the head of the bone entered the acetabulum, and there was a little shortening—about one-third of an inch—after reduction. In the former case there was no shortening at all immediately after reduction was effected. Extension was tried perseveringly, but the shortening remained; there was no crepitation; the motion of the hip-joint was free, and there was neither inversion nor eversion of the limb. The limb was put up with a long splint. After about a week he took off the splint himself in the night. It was not re-applied, and he never complained of pain again. There was no thickening about the head of the bone, and the shortening did not increase. He left the hospital in a month, with a very good limb.

Remarks by Mr. DOWNES.—It may be thought that the success was not very great in these three cases; for in the first case there was considerable shortening and great thickening about the joint; in the second, there was nearly an inch of shortening and some thickening; and in the last, though there was no thickening, there was one-third of an inch of shortening. It may be even thought possible that the reduction was not real, but possibly only a change of dislocation on the dorsum ilii to that in the sciatic notch; but I feel sure that this reduction was fully effected in all three cases, though I cannot explain the shortening and thickening which occurred subsequently in the two former cases. My reason for thinking this are—(1) that in the two least successful cases there was no shortening whatever, or, at any rate, extremely slight shortening at the time that the reduction was effected; (2) in all three cases the motion of the hip-joint was perfectly free after reduction, and in the two latter cases continued to be so; (3) there was neither inversion nor eversion of the limb at any time in any of the three cases.

Regarding the amount of success achieved, even in the first and least successful case no harm was done, on the contrary, he left with a better limb in every way than before the operation. In the last two cases the limbs were very useful ones when they left hospital, though on admission they were perfect cripples. The last two cases are further interesting because there are very few records of dislocation of the femur of such long standing having been reduced by

simple manipulation. The public fancy that bone-setters succeed in cases considered unfavourable by surgeons; but after the experience of these cases we should do well to be careful in deciding that a case is "best left alone," as in being over-rash. It may be observed that Orientals have not the muscular development of Europeans; their hip-joints also are very pliable, owing to their habit of always sitting down cross-legged; it is therefore hardly to be expected that the same successful results could be obtained in the case of Europeans with as little trouble as I had with my Kashmiri patients.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Dilatation of Central Canal of Spinal Cord.—*Pyocephalus.*—*Fibroid Tumour of Uterus.*—*Myeloid Tumour of Tibia.*—*Fatty Tumour of Larynx.*—*Fatty Tumour of Scalp.*—*Acute Necrosis of Tibia.*—*Osteitis of Femur.*—*Paralysis of Cranial Nerves in Congenital Syphilis.*—*Fracture of Coracoid Process.*

THE first meeting of the Pathological Society for the present session was held on Tuesday last, Oct. 19th. The President, J. Hutchinson, Esq., occupied the chair. The number of specimens exhibited was less than usual, but the interest of the meeting was well sustained throughout.

Dr. NORMAN MOORE showed three specimens. The first was a Spinal Cord removed from a woman, aged twenty-two, married, recently in St. Bartholomew's Hospital. Two years previously she began to lose power in the left arm, and eighteen months later in the right arm; she had complete power in the legs. There was partial and varying anæsthesia above the deltoid muscles. The breathing was hoarse, but there was no growth, thickening, or other obvious change in the larynx to account for it. Death occurred suddenly in an epileptiform attack. At the autopsy the ventricles of the brain were found greatly distended with clear fluid, and the central canal of the spinal cord was dilated to the size of the finger. The case was of interest from the small amount of symptoms produced by such an extensive change in the cord, and from the rarity of hydrorachis, apart from imperfection of the bony walls of the spinal canal. The second specimen was the Brain of a child, aged five months, who came to the Metropolitan Free Hospital with slight cervical opisthotonos; the eyes were normal. It was admitted into St. Bartholomew's, and ten days later the temperature rose to 101°2', and even to 103°6', and on the thirteenth day the child died in a fit. The child had been quite well till a week before it was seen, when it had a fit and cervical opisthotonos. The lateral ventricles of the brain were very much dilated, and each contained more than one and a half ounces of pus; their lining membrane was intensely injected; the pus extended also through the fourth ventricle into the sub-arachnoid space and canal of the cord, and there was abundant lymph around the medulla oblongata. Drs. Barlow and Gee have published twenty-five cases in which, after symptoms of slight cervical opisthotonos, the autopsy has revealed meningitis with lymph, especially about the base of the brain. Dr. Moore thought that his case showed a later stage of the same affection, and that the pyocephalus came on with the sudden rise of temperature. The third specimen was a large Calcified Uterine Fibroid, found by Dr. Godfrey of Jersey, while making the post-mortem in a case of cirrhosis of the liver. There had been no symptoms referable to the tumour during life.—Dr. F. TAYLOR had shown a spinal cord with a large cavity in it some time ago, and then had referred to the literature of the subject and found references to many similar observations. He asked if an examination had been made to prove the relation this cavity bore to the rest of the cord, for it was at present an open question whether these cavities are dilatations of the central canal, or arise from degeneration of the cord, or softened tumours. They are always seated towards the back of the cord involving the posterior columns. In most of the

cases the symptoms have been slight, or inconsistent with the extent of the cavity. Dr. Moore's case was the largest cavity he had seen or read of. In his own specimen the cavity extended from the mid-dorsal region to the lumbar enlargement, and there was a separate cavity in the neck, with dilatation of the ventricles of the brain. In some cases the central canal has been found separate from the cavity.—Dr. N. MOORE had only made a naked eye examination of the cord. He had previously seen a case in which there was during life loss of power in the arms, and post mortem a small cavity in the cord, which was evidently a dilated central canal.—Dr. EWART referred to a case of a woman of middle age who died from insidious ingravescent paraplegia, in whose spinal cord was found a cavity four inches long and a quarter of an inch in diameter, tapering at each end, and occupying the mid dorsal region. He had seen a less degree of the same change in a child.

Mr. MCCARTHY exhibited a specimen of Myeloid Sarcoma of the Head of the Tibia. Early in this year a woman, aged twenty-three, came to the out-patient room of the London Hospital, complaining of pain in the right knee. She was strumous looking, and appeared to be ill. On examining the knee there was nothing the matter with the joint, but on the inner side of the head of the tibia there was a small, irregular, painful and tender swelling; the skin over it was red, and fluctuation was to be detected. The woman was admitted to the wards and considered to be suffering from a suppurating bursa. The rest in bed quickly led to the disappearance of the redness, heat, and pain, though the fluctuation continued. A day or two later the swelling was found to pulsate, but this varied in intensity very much from day to day. There was no bruit, and if the femoral artery was compressed the pulsation ceased, but returned gradually on removal of the pressure over the artery. Blood withdrawn by a small trocar showed giant cells. Amputation was performed, and the application of Esmarch's bandage caused fracture of the head of the bone. On opening the joint it was found that the growth had spread up the crucial ligaments, and the lower end of the femur was therefore removed. Although treated antiseptically, the temperature continued high, and there was a very profuse discharge of dark thin fluid from the wound for several days, with excruciating pain on any movement. Death occurred from exhaustion on the twelfth day. At the post-mortem the wound was found to be nearly healed; the bone healthy; but the supra-patellar pouch of synovial membrane was found inflamed, covered with lymph and containing pus. Here lay the probable cause of death. The head of the tibia was entirely replaced by the tumour, except at the back, where a piece of bone one-sixteenth of an inch thick remained. The cartilages of the tibia were intact, but between the joint surfaces where there was no cartilage the tumour had destroyed the bone, and spread up into the crucial ligaments. The case was of interest, partly from the slight symptoms the tumour produced.—The PRESIDENT called attention to a fresh specimen of Myeloid Tumour of the Femur that he had placed on the table.—Mr. BUTLIN remarked that there were only two or three cases where the tumour had spread from the tibia to the femur through the crucial ligaments; he had seen one case where an ossifying round-celled sarcoma of tibia had thus grown, and the lower quarter or one-third of the femur was full of the tumour; as an example of the less degree of malignancy of these central tumours, he mentioned that he knew this patient to be alive and well four years and a half after amputation through the thigh.

Mr. SYDNEY JONES showed two Fatty Tumours. One was as large as a Tangerine orange, with a pedunculated attachment to the right aryteno-epiglottidean fold. It was met with in a man forty years of age; on opening his mouth nothing abnormal was seen, but when he gave a peculiar gulp the tumour was brought up and lay on the dorsum of the tongue. It was removed by freely dividing the mucous membrane of the pedicle and turning it out. A small cyst lined by stratified scaly epithelium was found in it. The other specimen is described in THE LANCET for Oct. 9th, page 587.—Mr. R. PARKER mentioned a small fatty tumour of the tongue which had been sent to him by the President.—Mr. MORRANT BAKER stated that a child was brought to the Evelina Hospital who by a gulp brought into the mouth a tumour the size of the thumb, which was attached to the soft palate by a broad pedicle. He ligatured the pedicle and cut off the growth, which consisted of fat fibro-cellular tissue and a central rod of cartilage. He

thought that possibly Mr. Jones's case was a foetal development of some kind long unnoticed.—Mr. MACCORMAC referred to a fatty tumour which he had removed from under the scalp over the parietal eminence. It was as large as a bun, weighed five ounces and a half, was firmly moulded over, and in places adherent to, the pericranium. The outer part of the tumour was pure fatty tissue, but in the centre of the mass was a cavity full of ordinary sebaceous matter. The patient was a girl aged fourteen, and the tumour had only been noticed two years previously, when it was the size of a bean.

Mr. MORRANT BAKER (for Dr. Gregory White of Bournemouth) showed a specimen of Acute Necrosis of the Tibia. A boy, eleven years of age, was struck on the leg with a fir cone; two days afterwards he complained of pain below the knee. On admission to the Bournemouth Cottage Hospital three days later the temperature was found to be 103°, and the skin of the upper half of the leg was red, glazed, and swollen; an incision was made, and pus evacuated; and subsequently a profuse discharge continued. A month later amputation through the thigh was performed. The specimen was a good example of osteo-myelitis with necrosis. Mr. Baker referred to the often trivial injuries alleged to be the cause of most severe osteitis, frequently accompanied by septicæmia, and ending fatally.—Mr. GODLEE thought that there was evidence of the constitutional, rather than purely local, origin of this disease, in that more than one bone was sometimes affected at the same time—as the femur and radius; that the children were usually ill for some little time before the local lesion appeared, and that often there was no history of injury whatever.—The PRESIDENT reminded the Society that Mr. Simon wrote some years ago on what he called "Necrosal Fever," and then pointed out that many bones might be affected. He himself had seen many examples of multiple necrosis, and had now under his care a girl who had lost nearly the whole of the shaft of one tibia, after which the tibia and humerus of the opposite side were attacked in a similar manner. He did not think that the children were always ill before the disease came on, but believed that there was always an injury, which might, however, be very slight. In this form of multiple necrosis one bone was attacked first, and the others subsequently, and, in his opinion, secondarily, as a result of the first—as truly so as is the case in infecting tumours. He had noted that the secondary form was never so severe as the primary, and that it was not very uncommon to find a threatening of suppuration, which was not carried out. He imagined that in such forms of inflammation there was a parallel condition to what is held to occur in new growths; that from the primary area of inflammation products were discharged into the blood current which lodged elsewhere, and set up the secondary disease. He had not seen a marked tendency to pyæmia in cases of multiple necrosis, though no doubt it may occur.—Mr. C. HEATH alluded to the multiple necrosis after typhoid and scarlet fevers, as evidence of the constitutional origin of necrosis. Mr. Marcus Beck, who had studied these cases closely, thought that there was a specific fever in acute necrosis; but Mr. Heath believed there was usually to be obtained a history of injury to a previously healthy child. He had sometimes thought multiple necrosis to be pyæmic in nature, but he had never found an abscess in the lung or liver in such cases.—Mr. GODLEE explained that he had not referred to a previous condition of chronic ill health, but believed that he had seen cases where there was fever before any sign of local mischief.—Mr. HOWSE asked what evidence there was of necrosis in this case.—Mr. BAKER replied, that there was a distinct central sequestrum almost separated from the rest of the bone. He had seen several cases of most acute septicæmia with acute necrosis, where there was a pustular eruption, pyopericardium, and death in about four days.—The PRESIDENT mentioned a case of acute necrosis of the clavicle, which had died exactly as Mr. Baker had described.—Mr. HEATH explained, that he was quite familiar with such cases; his previous remark had reference to cases of multiple necrosis in which he had not met with distinct evidence of pyæmia.

Mr. MORRANT BAKER also showed the lower half of a Femur removed from a patient in St. Bartholomew's Hospital suffering from abscesses and sinuses in the lower end of the thigh, with severe pain and hectic. Amputation was performed. The femur was very much thickened, with new bone thrown out both around and within it, but the outline

of the original shaft was still distinct. He thought it an example of the middle stage of osteitis. Referring to the common use of the term "expansion of bone," he remarked that there is no such thing as a marked separation of the lamellæ of compact bone, and that the condition so named was really due to a deposit of new bone from the periosteum and endosteum, with subsequent obliteration of the outline of the original bone. The condition of necrosis without suppuration, or intra-osseous necrosis, he held to be the outcome of a chronic osteitis, and not a sudden death of the bone. Previous to the amputation the man had had two attacks of hæmorrhage, and twelve hours after the operation he sank from continuous oozing of blood from the whole surface of the wound. He had seen other examples of this condition, which he thought was a traumatic hæmorrhagic diathesis; in several of the cases there was albuminoid disease.

Mr. NETTLESHIP brought forward a living specimen—a girl aged fourteen, of stunted growth, having distinct evidence of congenital syphilis. She was affected on the right side with partial anæsthesia of the parts supplied by the first and second divisions of the fifth nerve, complete paralysis of the sixth nerve, and partial of the third and fourth. There was also opacity of the cornea, old iritis, choroiditis, and probably retinitis; it was impossible to tell the exact condition of the optic nerve, but vision was fair. The right eye was apparently markedly smaller than the left, which might perhaps be connected with an obvious asymmetry of the bones. There was old keratitis and choroiditis on the left side, but no paralysis. He was unable to say whether the seat of the lesion was in the orbit or the cranium; there were no symptoms of disease in either.—The PRESIDENT stated that there had been many recent additions to our knowledge of brain and nerve disease in inherited syphilis. He himself had published two or three cases of ocular paralysis, but it was bilateral, giving evidence of a central origin; he had never met with a case where there was distinct evidence of pressure on the trunks of nerves.

Mr. SHATTOCK showed a specimen of Fracture of the Coracoid Process of the Scapula found in an elderly woman. The fracture extended obliquely back from between the attachments of the pectoralis minor and the conjoined biceps and coraco-brachialis muscles. The fragment was united by a broad band, and was not displaced. There was no sign of injury to the shoulder-joint. It was not a case of ununited epiphysis, because the line of fracture was not that of the junction of epiphysis and diaphysis, nor did the fragment include the whole process. There was no history to the specimen.

The following specimens were shown by card:—1. Cartilage Tumours in the centre of the ends of the Bones of the Metacarpus and Fingers—a drawing. 2. Congenital Solid Tumour on the end of Toe of Infant, adherent to the bone—a drawing. 3. Congenital Tumour on the end of Finger of Infant, containing a cyst with cartilage—a drawing. 4. Congenital Fibro-cystic Naevoid, tumour of the cheek in a child—a drawing. All by the President.

The meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

Recovery from Symptoms of Organic Brain Disease.

THE first ordinary meeting of the 108th session of this Society was held on the 18th instant, F. J. Gant, Esq., President, in the chair. In the course of his opening remarks the President reminded the Fellows of the projected meeting of the International Congress in London, and stated that no efforts would be spared to make that gathering an historical success.

Dr. HUGHLINGS JACKSON then read a paper on a Case of Recovery from Symptoms of Organic Brain Disease. The case was one of supposed hysteria, double optic neuritis with nearly complete blindness, severe headache, no vomiting, loss of smell; no deafness; reeling gait; absence of patellar-tendon reflex; doubtful lightning pains. Recovery under mercurial inunction, except of anosmia and absence of patellar-tendon reflex. The patient was a well-nourished woman, twenty-two years of age, admitted into the London Hospital on Dec. 22nd, 1879. Menstruation was regular;

there was no evidence of syphilis. In August, 1878, she was run over by a cart, her legs being injured above the ankles. In May, 1879, she went into service, and was quite well except for a "weakness in her legs." This "weakness" increased, and two days before admission she could not stand at all, and took to her bed. During the week before admission there was a weakness of the right arm, which would "go and come;" afterwards "pins and needles" in this limb, and then weakness of the left arm set in. Her sight began to fail two or three weeks before admission. *Symptoms of local gross organic disease:* (a) double intense optic neuritis (with mere perception of light); (b) intense headache, from the misery of which she was silent and very quiet. On her recovery it was ascertained that smell was entirely wanting. She averred that she used to smell well before her illness. Dr. Jackson was doubtful whether anosmia was in her case a localising symptom or not. It may have been owing to pressure, direct or indirect, on the olfactory bulb; or, what is quite hypothetical, to an olfactory neuritis. *Localising symptoms:* (a) absence of patellar-tendon reflex—an exceedingly important symptom, especially as her gait was abnormal, without paraplegia. The reflex was still absent when she left the hospital on March 25th. It may have been so long before she had the other symptoms, but of this nothing could be learnt. (b) Pains in limbs. At one spot a little above the left knee she had occasionally a dart of sharp pain, followed by a dull aching; it would come and go. She had no severe pain except in the head. It could not be averred that the pains were those characteristic of posterior sclerosis. (c) Reeling gait. This was noted carefully. When admitted she could scarcely walk at all, and not without help. Her gait then was not like that of locomotor ataxy. As she improved a little it could be better analysed. It was evidently a reel—a drunken-like walk. Apparently she had good power in her legs, and, using popular language, though inexact, there was "disorder" of coördination without "paralysis." (d) Other symptoms. There was some slight weakness of the left arm, with a slightly feeble grasp. These symptoms were very slightly marked. Some tenderness of the lower part of the spine was found. No very local tender spinal spot was revealed, either by the application of a hot or cold sponge, or by manipulation. There was no spinal curvature, no atrophy of any muscles, no defective sensation, and no vesical trouble of any kind. Progress: rapid recovery. Iodide of potassium was at first prescribed in doses of five grains three times a day; but on January 4th mercurial inunction was ordered in addition. The dose of the iodide was smaller than that usually given in such cases. Under this mixed treatment she rapidly improved. From what was practically blindness she became able to read on January 26th No. 1 of Snellen at six inches with her left eye, but with the right only No. 3. On the day of her leaving the hospital, March 23rd, she could read No. 1 very easily with her left, and with slight difficulty with her right eye. Practically her sight was quite good. She felt well, and except that the patellar-reflex was still absent, and that she could smell nothing, she was considered to be free from symptoms. Dr. Hughlings Jackson then considered the case from several points of view. He referred to cases of recovery from symptoms induced by tumour of the brain; cases in which after little illness there was post-mortem evidence of tumour. He discussed also the question of syphilis, pointing out that a syphilitic tumour sometimes gave rise to symptoms similar to those produced by glioma or other "foreign body." He did not think that the mere fact of his patient's recovery under anti-syphilitic treatment necessarily over-ruled the conclusion that the intra-cranial disease was syphilitic. He spoke of the importance of the routine use of the ophthalmoscope, both as sometimes negating the diagnosis of hysteria, and also as leading to early treatment.—Dr. ALTHAUS said the great difficulties in diagnosis of brain disease could be traced to two classes of cases—viz., those in which coarse lesions, as hæmorrhage, softening, abscess, atrophy, and tumours were found after death, yet no symptoms had existed during life; and others in which the gravest symptoms, pointing to severe organic changes, were observed, and the patients recovered under treatment. He alluded to hemi-anæsthesia occurring from disease of the posterior part of the internal capsule, and the same affection as occurring in Charcot's hystero-epileptic women, in whom the disturbance was purely functional. He also related a case resembling in many points that described by Dr. Jackson, and in which he had made the diagnosis of

tumour in the right cerebral hemisphere. In this case the administration of mercury and iodide of potassium led to recovery, although the patient had never shown any symptom of syphilis.—Dr. BROADBENT remarked upon the interest and value of the communication, the case affording Dr. Jackson an opportunity for the refinements in diagnosis which he had placed so clearly before the Society. He had, no doubt, seen many instances of recovery from far more serious symptoms of organic disease of the brain, as had Dr. Broadbent and others; and in this case the symptoms formed a distinct category, indicating the seat of the disease, and no one would doubt his diagnosis of a coarse lesion in or affecting the cerebellum. Dr. Broadbent thought the course of symptoms and rapid recovery were best explained by supposing the lesion to be syphilitic, and he cited a case of a young woman, recently under his care, suffering from headache, vomiting, convulsions, double optic neuritis, and paralysis of the left third nerve. She had certainly not acquired syphilis, but there was a scar on her forehead of a suppurating node (which had not healed until she took iodide of potassium), and no doubt she was the subject of hereditary syphilis. She rapidly recovered under large doses of the iodide; but about twelve months after was readmitted with paralysis of the right sixth and seventh nerves. He had also under treatment a case of hemiplegia in a young man, obviously due to inherited syphilis. The loss of patellar-tendon reflex was presumptive evidence of syphilis; for, as Dr. Gowers had recently stated, probably 75 per cent. of cases of locomotor ataxy were due to syphilis; and this case might be one of incipient ataxy. With regard to optic neuritis, he confirmed from many cases the fact so often insisted upon by Dr. Jackson, that this may exist without noticeable affection of sight; and in the present case he was inclined to attribute the blindness to pressure on the optic tracts or nuclei by the disease in the cerebellum. He held the view that optic "neuritis" was really ischæmia, due to strangulation of the nerve and its vessels just behind the eyeball, by effusion into its sheath; and he believed the neuritis, with numerous hæmorrhages (not, of course, the ordinary albuminuria retinitis) seen in some cases of renal disease, had the same causation.—Dr. DOWSE asked whether Dr. Jackson had met with the absence of patellar-tendon reflex when no actual posterior sclerosis existed; and said that in his opinion the phenomenon might be due to inhibition.—Dr. JACKSON replied in the negative.

MEDICAL OFFICERS OF HEALTH SOCIETY.

AT a meeting of this Society, on Wednesday, Oct. 13th, held at 1, Adam-street, Adelphi, the President, Dr. Bristowe, delivered the inaugural address of the session.

Referring to a promise made at the beginning of the last session, Dr. Bristowe said the subject of his address would be to discuss relations of medical officers of health to their duties. Dr. Bristowe said any intelligent layman would believe that if the mortality of a certain district was exceptionally high the sanitary authority of the district had neglected its duties. If it were shown to him that the deaths were due to diseases over which a sanitary board had no control, he would probably acquiesce under protest, and take his final stand on deaths from infectious diseases. It would not be easy to convince him he was in error, and if he were convinced he would say "I convict you of incompetence to deal with those matters of which sanitary science professes to take cognisance." Dr. Bristowe did not agree with this argument or conclusion, but considered that sanitary science had done much to diminish the prevalence of small-pox, cholera, and enteric fever.

The practice of vaccination has reduced the mortality from small pox to a degree which it is almost impossible to appreciate, and these benefits are maintained even though weak-kneed politicians not only hesitate to make vaccination strictly compulsory, but actually seem to contemplate the granting (as Sir W. Jenner puts it) of licences to contract and propagate disease. We have power to enforce a single effectual vaccination, but even this may be evaded by any parent who chooses to pay a fine or undergo imprisonment. It is essential that the operation be repeated at the age of puberty. The only effectual remedy is to revaccinate all those who are exposed to contagion. If infantile vac-

cination and revaccination at early puberty were made absolutely compulsory, and if, when small-pox has broken out in a house, revaccination were made compulsory on the members of the household, epidemics of small-pox would never arise, or would be strangled in their birth.

The poison in enteric fever is contained mainly in the alvine discharges of patients. It is by the pollution of water and food that the disease is propagated. Improvements in our system of drainage have involved diminution of enteric fever in London. That enteric fever is the one disease in regard to which medical officers of health are directly serviceable is beyond dispute.

The prevention of cholera constitutes one of the greatest sanitary triumphs resulting from the almost complete abolition of superficial wells and the presence of a purer water supply.

We have no special proof that the contagion of diphtheria resides in the emanations from sewers.

Our powers of enforcing disinfection are interfered with by the apathy and antagonism of those whose duty it is to aid. In the great majority of cases no information, except in case of deaths, reaches us; doctors and the family prefer to hush the matter up.

Among other diseases which kill are inflammatory diseases of various kinds. The removal of dampness tends to improve the health of inmates, but the influence of damp rooms is little compared with that of daily exposure to cold and draughts on the doorsteps and in the gutter.

Mortality tables are invaluable guides to us in the performance of our duties; they yield important information upon the distribution of diseases and the time of their occurrence, but they must not be at once accepted as evidence of the influence of sanitary labours.

The relations of medical officers of health to the vestries or district boards which employ them is a matter of great importance. It is doubtful whether any advantage would be gained by making the appointments of medical officers of health permanent; if the salaries were not assured to them they could easily be got rid of by the diminution or discontinuance of the salaries, and it would be difficult to enforce the sanitary laws in the teeth of those who are placed in authority, nor in the metropolis has there been a case in which the vestries have exercised their powers arbitrarily or unjustly.

To a considerable extent medical practitioners look with suspicion upon health officers: it behoves the latter not to do anything to justify attitudes of this kind.

In conclusion, Dr. Bristowe pointed out that it is not the law which gives the medical officer of health the chief power for good, but the moral influence he acquires amongst those for whom, and with whom, he acts.

Reviews and Notices of Books.

On Atrophy of the Stomach and the Nervous Affections of the Digestive Organs. By SAMUEL FENWICK, M.D., F.R.C.P. Lond., Physician to the London Hospital. London: J. and A. Churchill. 1880.

PERHAPS more errors occur in the diagnosis of stomach affections than in the case with the diseases of any other organ. It is true that where "coarse" pathological changes have taken place, such as ulcer, cancer, or chronic gastric catarrh, there is generally little difficulty in arriving at a definite conclusion as to the nature of the lesion; but where the alterations of tissue are not so well marked, and where the mischief seems chiefly to arise from qualitative and quantitative changes in the composition of the gastric secretions, then it is we find a difference of opinion often expressed. In the present volume Dr. Fenwick presents us with a series of cases which will, we believe, serve as a useful guide to many who are called upon to decide upon the real nature of some of these "obscure" stomach affections. The chapters relating to atrophy of the stomach will be read with much interest, and Dr. Fenwick has already added considerably to our pathological knowledge in this direction. In the cases cited by him the atrophy was undoubtedly a morbid condition, manifesting itself primarily in the walls of the stomach,

and not accompanying or induced by any other disease. In all, the symptoms were remarkably similar, as was the morbid condition of the stomach discovered after death. The patients were all males varying from forty-five to sixty-two years of age, a time of life in which the vital powers begin to fail, and when degeneration of tissue is most likely to take place. Marked anæmia was noticed from the first; microscopic examination of the blood, however, showed no increase in the number of the white corpuscles, and no abnormal appearance could be detected in the coloured cells. Dr. Fenwick also discusses the relation of gastric atrophy to other forms of "idiopathic anæmia," and throws out a hint that some explanation may be found for the anæmia in Addison's disease as the result of changes in the gastro-intestinal canal. These changes, Dr. Fenwick believes, are of the nature of chronic gastro-intestinal catarrh; the attacks of vomiting, one of the earliest symptoms of the disease, the want of appetite, the cardalgia, and the diarrhoea which is usually such a prominent symptom, point conclusively to the presence of this condition. Admitting, therefore, that chronic gastro-intestinal catarrh is invariably present in Addison's disease, it becomes necessary to inquire how it is to be accounted for. Dr. Fenwick believes it to arise from interference with the function of the nerves supplying the gastro-intestinal tract, caused by disease of the supra-renal capsules. For if, as he observes, section of a sympathetic nerve causes the dilatation of the vessels of the part to which it is distributed, we can see that the morbid state of the nerves and ganglia of the stomach and intestines will be apt, if our present physiological doctrines be correct, to give rise to permanent catarrh of these structures. The other phenomena of the disease, Dr. Fenwick remarks, seem to lend support to this view, especially the failure of the heart; and he arrives at the conclusion, which has also been entertained by others, "that death in Addison's disease is not the result of an interference with the functions of the supra-renal bodies, but that it arises from the destruction of the numerous and important nerves that are situated in their vicinity." Dr. Fenwick's remarks upon atrophy of the stomach in persons affected with cancer of various organs will be read with interest and profit. In the consideration of the nervous affections of the digestive organs the author approaches debateable ground. He cites some very interesting cases of "anorexia nervosa," a disease first described by Sir W. Gull under the term "apepsia hysterica," and subsequently by Dr. Wilks. No pathological explanation has hitherto been forthcoming to account for the strange inappetency. Dr. Fenwick, however, very plausibly suggests that it may be due to either "anæsthesia or a perversion of the sensibility of the nerves distributed to the stomach, analogous to what we sometimes observe with respect to the cutaneous nerves in hysterical females." Idiopathic neuralgia of the stomach and abdominal viscera is an affection on the existence of which some physicians have expressed doubts, holding that frequently recurring pain, localised to one particular spot, is generally found to be the result of actual disease. This view, however, cannot be accepted by those who have had experience of malarious diseases; intense neuralgic pain, accompanied by rigors and followed by sweating, and yielding to treatment with quinine and arsenic, is not infrequent in persons living or who have lived in malarious districts. Many of Dr. Fenwick's cases were of this nature. The concluding chapter treats of the gastric neuroses of the vaso-motor system; two out of the three cases given in illustration seem to us in their character closely to resemble the *crises gastriques* which often precede or accompany the development of ataxic symptoms.

In conclusion we congratulate Dr. Fenwick on the production of a work which, while interesting to the pathologist, is of greater value to the practitioner as presenting him with a clinical account of some of those obscure affections of the stomach which are constantly coming under his notice.

An Atlas of Human Anatomy. By RICKMAN JOHN GODLEE, M.S., F.R.C.S., Assistant Surgeon to University College Hospital, and Senior Demonstrator of Anatomy in University College. London: J. and A. Churchill. 1880.

WE have already noticed the earlier numbers of this excellent atlas, but we must congratulate Mr. Godlee on its completion, and on the improvements in the later plates. Some of the earlier drawings were scarcely as distinct as we could have wished, but in the more recent ones no trace of imperfection exists; and for accuracy, clearness, and intelligibility they leave nothing to be desired. The series, which consists of twelve parts containing forty-eight plates, will form a most excellent guide to the student whilst dissecting, and its study will do much to bring back to the advanced practitioner anatomical details which may have escaped his memory. He will thus be materially aided in planning the steps of an operation or in arriving at the diagnosis of a difficult case. The parts are all represented half the natural size, and although some would appear less complicated if somewhat larger, we must allow that this uniformity has in other respects great advantages. The explanatory text is concise, well written, and contains many valuable suggestions for the surgeon. Mr. Godlee's labour of four years has been well bestowed, and editor and publishers deserve great credit for having added so useful a work to English anatomical literature.

Anatomy, Descriptive and Surgical. By HENRY GRAY, F.R.S. Ninth Edition, by T. HOLMES, M.A. Cantab., Surgeon to St. George's Hospital, &c. London: Longmans, Green, & Co. 1880.

GRAY'S Anatomy is so deservedly popular and well known that it is unnecessary for us to do more than call attention to the issue of this new edition. It differs but little from the preceding, except in some corrections in points of detail and in containing some illustrations from Klein's Atlas of Histology. The artistic finish of the illustrations in the early editions was so prominent a feature that we are sorry to see badly-executed drawings—such as Nos. 370, 394, and 438—perpetuated in the later editions. We would suggest that these should be replaced in the next issue by figures which a little extra care in the drawing and shading would make much more intelligible to the student, and more worthy of a place in Gray's Anatomy.

Spirit Gravities, with Tables. By THOMAS STEVENSON, M.D. Lond., Fellow and Examiner in Chemistry of the Royal College of Physicians of London; Examiner in Forensic Medicine in the University of London; Lecturer on Chemistry and on Medical Jurisprudence in the Medical School of Guy's Hospital, &c. London: Van Voorst. 1880.

THESE tables are similar to those of Mr. Hehner which we lately noticed. Mr. Hehner, however, based his on the determinations of Fownes, whereas Dr. Stevenson adopts the older experiments of Gilpin, confirmed in part by Drinkwater. Dr. Stevenson adduces reasons which appear to us satisfactory for his choice, and draws attention to one or two points of ambiguity in Fownes's otherwise excellent experiments. The two sets of tables differ by little, the highest variation, and that an exceptional one, being about 5 per cent. of proof spirit. Gilpin's work is known to have been admirably executed. It is, indeed, really marvellous when we consider that it was done nearly ninety years ago.

ABERDEEN UNIVERSITY COURT.—At a meeting held on the 12th inst., the following gentlemen were appointed examiners for graduation in medicine for the forthcoming year:—Dr. W. J. Walsham, London; Dr. Robert Smith, London; Dr. F. Buchanan White, Perth; Dr. J. W. Miller, Dundee; Dr. David Greig, Dundee; and Dr. John Barclay, Banff.

The Lancet Commission ON THE MEDICAL USE OF WINES.

IV.—RED BURGUNDY WINES.

THE numerous red wines from the Cote d'Or, although not so widely known or so much consumed in this country as the clarets from the Gironde, are great favourites with connoisseurs, and secure a large, though perhaps a somewhat more select sale. By many authorities the Cote d'Or is thought to be even more favourably circumstanced for the cultivation of the grape than the claret district; its soil is remarkable for the large quantity of iron with which the carbonate of lime is pervaded, and some consider this of exceptional importance in developing the perfect characteristics of the grape. Burgundy wines are deeper in colour, more full-bodied and generous, and possess a more typically vinous, if somewhat less delicate, flavour and bouquet than other red wines of similar quality and price. As a rule, they suffer from the disadvantage of not preserving their best qualities beyond a certain age, for after ten or twelve years keeping many of them become somewhat thin, although Santenay and Corton wines are exceptional in this respect, and retain their especial characteristics for a much longer period. Hence, although the best vintages of late years are probably those of 1865 and 1868, yet wines of 1870 are now in excellent condition; and those of 1874-75-76 are very fair samples, and will still further improve. Almost every village in the Cote d'Or gives its name to a wine, but for practical purposes, medically, they can best be taken in three classes. The cheap Burgundies are either the ordinary red Burgundies, such as inferior growths of Mercurey and Beaune, or very new specimens of some of the higher-classed wines. The better Beaunes, and the wines of Nuits, Volnay, and Pommard, form a second group. Corton may be taken as a link between this division and the highest, although very fine specimens of Volnay make the latter a dangerous competitor for pride of place. The superior Burgundies include some of the grandest wines that are known, such as Romanée, La Tâche, Richebourg, and Musigny, in addition to the better known Chambertin and Clos-de-Vougeot. From the adjacent districts of Mâcon and Beaujolais a large quantity of wine is now imported, and as these are popularly, though erroneously, classed with the true Burgundies, it will be most convenient for us to discuss their medicinal value at the same time. Whilst a few of them are really first-class wines, the majority are cheap and more suited for ordinary use, and hence come into competition with the cheaper clarets and Burgundies than with the more select varieties of these wines. Besides ordinary Mâcon, Moulin-à-Vent and Thorin wines are the best known of that group; from the Beaujolais districts those from the vineyards of Chénas, Fleurie, and Morgon are almost the only ones known by distinctive names in this country. The wines of Mâcon and Beaujolais are derived mainly from a different kind of grape from that which is most cultivated in the Cote d'Or; they are paler in colour, less spirituous, possess less body, and are more astringent than the true Burgundies. They are usually considered to occupy an intermediate position between the clarets in ordinary consumption and the less expensive of the red Burgundies, &c.

Typical examples of Mâcon [submitted by C. Ward and Son] and of Beaujolais [Gallais], both of 1875 vintage, and at 24s. per dozen, were analysed. The former, though a full-bodied wine, was remarkably soft and delicate to the palate, whilst the latter was very astringent, although a very sound wine, and without any trace of acidity.

The Beaujolais showed a very marked proportion of tannin, but this was less than in some of the clarets we analysed. The amount of grape-sugar and of fixed acid was not excessive, and the percentage of alcohol very little more than that which is generally found in clarets. The more generous character of these wines will recommend them to many, and there is no reason why they might not be drunk in all cases in which we have recommended red clarets. Beaujolais is of course preferable when a wine of marked astringency is indicated.

For purposes of comparison we selected a true Burgundy wine, rather new, but sound in quality, and with a full vinous flavour [submitted by James Campbell], and marked 18s. per dozen.

Fixed acid ...	...	.31
Volatile acid ...	...	.27
Tannin ...	...	.13
Absolute alcohol { by weight ...	...	9.64
{ by volume ...	...	11.96

The amount of total solids is very small, as in some of the clarets, whilst the percentage of alcohol is rather larger than in the Mâcon, and almost the same as in the Beaujolais. The tannin is very small, and in other respects no well-marked difference could be detected.

Higher-priced Burgundies—viz., Beaunes, Pommards, and Volnays, vary from about 30s. to 50s. per dozen, and many excellent specimens were submitted by various merchants [Fearon, Feltoe, Ward, &c.]. They were typical, full-bodied, high-flavoured wines. Any of them might be taken with advantage in suitable cases, and it is especially from this class that conclusions on the medical use of red Burgundy should be drawn. Medicinally they have little to differentiate them from one another, although age, bouquet, and flavour will have much influence in determining a personal choice. An analysis of a very good Beaune [Ward] of 1875 vintage at 34s. per dozen gave the following results:—

Total solids ...	...	1.78
Grape-sugar ...	...	.07
Fixed acid ...	...	.33
Volatile acid ...	...	.22
Tannin ...	...	.19
Absolute alcohol { by weight ...	...	9.57
{ by volume ...	...	11.87

As superior examples we should also include two specimens of Corton, remarkable for delicacy and softness—one of 1874 vintage [Burgoyne], at 48s. per dozen, and another more expensive of 1870 vintage [Ward].

The highest priced first-class Burgundies range from 80s. to 120s. per dozen, and these, of course, include the finest wines of France. Their expense almost precludes their being prescribed medicinally; but as they may exceptionally be of importance, we analysed two varieties. They were both wines of superior merit, and in every respect worthy of especial praise. One was a Chambertin of 1870 vintage, at 78s. per dozen, grown by Groffier, of Vôsne-Romanée [submitted by Campbell], and the other was a Romanée of the same vintage, at 84s. [Fearon & Sons].

The chemical characteristics of these grand wines are, the increased percentage of alcohol, the almost complete absence of sugar, and the low proportion of tannin. For diabetic patients who can afford so expensive a luxury, these high-class red Burgundies appear to be especially well fitted.

The therapeutic value of red Burgundy wines is very marked, but the potency of their effects must make physicians somewhat cautious in recommending them, although in many types of disease no class of wine will produce so great benefit. They are well fitted for convalescents from fevers and other acute affections, and are superior to all

other wines in cases of anæmia, general debility, feeble development, and cases of mal-nutrition not depending on gastric or intestinal irritation. Even if such be present, they may frequently be prescribed with benefit, although lighter, and especially sparkling wines agree better if the irritability be a marked symptom. In most cases in which iron and cod-liver oil form the routine treatment, a wine-glass or two of good Burgundy with dinner is an excellent adjuvant. Primarily somewhat stimulating, these wines in their after-effects are markedly sedative, and hence many patients, weak in physical powers, but excitable and highly nervous in temperament, derive more good from them than from other classes of wines. In some cases this sedative influence may render unnecessary the ordinary soporifics, and chloral, opium, and bromides be now and again dispensed with. They do not aid the digestion as clarets often do, nor can they be taken as refrigerants; in fact, Burgundy is a very powerful wine, must be ordered with great care, and taken in small quantities only. It is said to favour the development of obesity, but we much doubt if this be a fact when the wine is taken in medicinal quantities. The excessive eating with which Burgundy-drinking is so generally accompanied, has, perhaps, as much to answer for in the production of this condition as the mere consumption of the wine. It is stated that in the Burgundy districts gout is not a prevalent disease, even among the growers and exporters of the best wines; but gouty patients can only take it sparingly, if indeed it be ever advisable. Bilious and plethoric people cannot take this class of wine with safety, and in many of these patients headache and a sense of fulness and discomfort are induced by even small quantities. The amount of sugar is so small that it may be safely ordered for diabetics, and the superiority of the best wines in this respect has already been referred to. The amount of fixed acid is much the same as in clarets; this, with the lower percentage of grape-sugar, make it even more valuable in many cases of rheumatism and neuralgia. It is important to remember that the best red Burgundies contain more alcohol than the corresponding clarets; and that in even the cheaper varieties, including Mâcon and Beaujolais, a similar difference exists. White Burgundies of the highest class, such as Montrachet, contain even more alcohol than Romanée or Chambertin, and as a large amount of unfermented grape-sugar is also usually present in such wines, they are indicated in different cases of disease, and cannot be safely substituted for one another.

NEW ENTRIES AT THE MEDICAL SCHOOLS.

THE following are the returns of the new entries at the medical schools of London and the provinces. When not otherwise specified, the number given must be understood to include all kinds of entries. St. Bartholomew's, as usual, heads the list, with a total of 170 new students, 20 of whom have entered to hospital practice or to special courses of lectures. Next comes the London Hospital, with 137, of whom 53 are special. Then follow University College, with 101 (in addition to 50 students preparing for Preliminary Scientific M.B. Examination of London University); Guy's, with 101 (11 special); St. Thomas's, with 91, of whom 55 are first-year's men; King's College, 69 (60 first-year, 9 second-year); St. George's, 61 (44 first-year); Middlesex, 50 (33 full curriculum); Charing-cross, 45; Westminster, 23 (3 partial). Of the Provincial Schools, the Cambridge school counts 57 students actually dissecting, 30 of these for the first time; the University of Durham College of Medicine numbers 54 new entries—29 full, 25 partial; Leeds has 41 (1 dental); Bristol 26 (4 partial); Queen's College, Birmingham, 22.

KING'S COLLEGE MEDICAL DEPARTMENT, ENTRANCE SCHOLARSHIPS.—Mr. John Power, Mr. Gray, and Mr. Thomas Arthur Collinson have been each awarded a Warneford Scholarship of the value of £75; and Mr. Charles Robert Hodges, one of £50. Mr. Ernest Pane Alphonse Mariette has obtained a Sambrooke exhibition of £60 for proficiency in General Literature and Science; and Mr. Albert Carters a Clothworkers' exhibition in Science of the value of £50.

THE LANCET.

LONDON: SATURDAY, OCTOBER 23, 1880.

"WITH a cause which in itself was unassailable, the medical staff have thrown away their advantages by injudicious letter-writing; and they have now no choice but to accept, for a time, the false position in which they have placed themselves." This is how *The Times*, which may be regarded as an exponent of the calm judgment of the community on the main question at issue, views the situation at Guy's Hospital; and the following is the opinion formed by the same impartial authority as to what the situation described practically involves. "According to the position they have taken up, they must submit to the risk of seeing injurious rules enforced, of seeing patients maltreated, of seeing the treasurer and the matron deciding, ignorantly and therefore often wrongly, on purely medical questions." It would be difficult to indicate a state of matters more unsatisfactory or humiliating, and, we fear, the utterly disastrous nature of the position apparently accepted by the medical staff of this hospital is not exaggerated in this outlook.

We are not in the confidence of the medical staff of Guy's Hospital, for the obvious reason that whatever other excellent qualities they may possess they have no confidence in themselves, probably because they have no confidence in each other. If the little band at Rorke's Drift had not held together, but each gallant member of the shattered corps had elected to fight the battle his own way, from his own personal coign of vantage, and with a special eye to his own safety, the result would not have been either creditable or satisfactory. This is what the physicians and surgeons attached to Guy's Hospital have been doing, and the result of the policy adopted is precisely what everyone who knew what was going on must have anticipated. We had in our possession on Wednesday last information which rendered the course taken by the Governors at their meeting of Thursday inevitable. The staff had hauled down its flag on the matter of principle by withdrawing a letter which, if not altogether wisely worded, was in fact and spirit a simple and manly statement of the facts, and the Governors had determined among themselves to make the most of a submission instigated, as they assumed, by a selfish fear of the consequences, from a body of professional men who had rashly taken up a position of defiance they were not prepared to defend. The medical staff of Guy's Hospital is composed of men for whom individually we, in common with the whole profession, have the highest respect, but as a body entrusted with the guardianship of public and professional interests, and accidentally placed in a position wherein they stood charged with the matured judgment of the medical profession on a question affecting the interests of the sick poor, at a great crisis in the history of hospital management, they have conspicuously failed. We will not say that they have betrayed their trust, but it has slipped from feeble hands palsied by the fear of the tempest their own rashness and want of tact had raised.

What remains to be done in the emergency? Is the medical staff of Guy's, as a body, content to carry on the medical business of this institution while the Governors, according to the express terms of their resolution, "maintain in its integrity the power to govern the hospital entrusted to them by law." It is *practically* a condition of the withdrawal of the resolution which "required" the senior physician and the senior surgeon to resign, that the subsequent resolution, by which the Governors virtually declare their intention to persist in the system of management of which the staff complained, "must be accepted by the medical staff." The withdrawal of the demand for resignation was an act of grace following upon the "unreserved" submission of the vanquished. Under these circumstances, we wait to see what course the staff as a whole, and Dr. HABERSHON and Mr. COOPER FORSTER individually, will elect to pursue. If, as we hinted last week, it had been a condition of the new start in this painful business that the Governors should acknowledge their error in attempting to manage a medical institution without medical aid, it might have been expedient to try the experiment of life and work under the existing *régime*; but no such acknowledgment has been made. On the contrary, the Governors have formally declared their determination to "maintain" their position. The only change in the situation is that the medical staff has abandoned the ground which it had taken up.

This is a true statement of the facts. It is idle to pretend that any new light has been thrown on the nature of the overtures made to the Governors when they consented to admit two members of the staff to the Taking-in Committee. All that is now *known* as to the status to be accorded to the representatives of the medical faculty at this subordinate board was known, or might have been known, months ago, when the original proposition was discussed; and, when taking a moderate view of the then situation, we counselled the staff to accept the proposals made to them. Subsequent events have shown that the relations between the medical staff and the Governors were, even at that time, so strained that a mutual understanding was impracticable. In short, the medical faculty at Guy's has allowed itself to be fretted and cajoled into a position wholly incompatible with self-respect, and the sooner and the more boldly it cuts itself adrift from a false and unsafe mooring the better will it be for its own reputation, and the credit of the profession to which its members belong. The policy and action of this body, as such, are unworthy of the distinguished reputations of its members as individual physicians and surgeons. It seems to have been embarrassed and misled by want of confidence in itself and in the profession. The interests of the sick poor, which are directly involved in this controversy, ought to have been paramount. The fate of the hospital, of the school, and of the physicians and surgeons attached to the hospital and the school, respectively, should have been left out of the question of policy. All responsibility as to the institution and the pupils would have devolved on the Governors if the medical staff had simply and boldly pursued the path of duty. If the Governors had closed the hospital, and broken their business contract with the pupils, the issue raised would doubtless have been adjusted. In any event, these were questions for the Governors, not for the staff.

The medical profession does *not* counsel the medical staff

of Guy's Hospital to carry its policy of submission farther. Public opinion will *not* justify the surrender of the interests of the sick poor. The principle which demands medical control for a medical charity is one which cannot be asserted and waived at will. The practical proposition that *nursing* is an integral part of treatment, to be performed under medical direction, and not to be regarded as a specialty entrusted to a separate department, is too obvious to be gainsaid or lightly set aside. In brief, the issues at stake are too great and too grave to be trifled with. If the medical staff at Guy's Hospital would retain the respect of the profession and the public as a representative body of medical men, it must pause before it decides to accept a compromise which is not merely humiliating, but cripples while it degrades.

WE are glad to learn on the best authority, that of the Vestry Clerk of St. Pancras, that the reports, published in several of our leading daily contemporaries, of a recent meeting of the Sanitary Committee of that parish, were entirely fallacious in attributing to Mr. SHIRLEY MURPHY, the local medical officer of health, a statement that the London registrars were in the habit of registering deaths without medical certificates in a wholesale manner. It appears that in fact Mr. SHIRLEY MURPHY only made a representation to his sanitary authority, deploring, as we have done again and again, the imperfect and dangerous condition of registration law, which permits the registration of any deaths without the production of a medical certificate, or other satisfactory evidence of the true cause of death. Reforms of all kind are too frequently retarded, instead of promoted, by exaggerated statements of the evils to be redressed, and on this account alone we regretted the over-statements which were last week falsely attributed to Mr. SHIRLEY MURPHY with regard to the registration of uncertified deaths in London. We rejoice to see that he, as well as one or two of the medical officers of health of Wandsworth District, has formally brought this important matter before the local sanitary authority; and we trust that every other medical officer of health will do his utmost to impress upon his sanitary authorities this dangerous flaw and laxity of registration law, as a preliminary step to pressing upon the Government, through the Home Secretary or the President of the Local Government Board, the necessity for further legislation which shall secure the due certification of all causes of death previous to registration. It is eminently desirable, however, that with a view to bringing the matter before the Government, by deputation or otherwise, some agreement should be arrived at as to what remedy ought to be proposed for the present dangerous and unsatisfactory state of the law. It should in the first place be clearly understood that nothing short of new legislation can effect the desired reform, as the Registrar-General and his local registrars are powerless, under the present state of the law, either to obtain medical certificates concerning a certain proportion of the deaths that occur, or to refuse to register such deaths because no such certificates are forthcoming. Neither has the Registrar-General any authority to secure the holding of inquests in cases where no satisfactory evidence of the cause of death can be obtained. The only means under the present state of the law to obtain evidence of the cause of an uncertified death is the holding of an inquest, but it is

very rare for a coroner to hold an inquest with this object. We have good reason for believing that most of the best registrars would gladly be spared their present unpleasant responsibility in the matter of uncertified deaths; they are instructed to refer all cases of death from violence, as well as all cases attended by suspicious circumstances, to the coroner before registering the death. It is, however, impossible in very many cases for the registrar to know whether there are any "suspicious circumstances" connected with an uncertified death he may be called upon to register. Coroners, moreover, seldom give a certificate concerning a case brought under their notice, in which they consider an inquest unnecessary, which would alone afford satisfactory evidence that the registrar had acted in accordance with his instructions. Registration in London is more efficiently carried out, as regards the certification of causes of death, than in the provinces, on account of the small proportion of unqualified medical practice in the metropolis. In devising a system for the certification of those deaths which now remain uncertified, it should therefore be remembered that in Wales and in some parts of England the proportion of uncertified deaths, instead of being less than 1 per cent., as it was in London last quarter, is 12 per cent. and upwards. It is evident that the expensive formality of an inquest cannot be necessary in so large a proportion of cases, and yet it is as certain that the present system is fraught with the gravest dangers. It will be wise to urge upon the Government when the coroners question is dealt with, as it must be ere long, that the questions of uncertified deaths and of apparently unnecessary inquests should be fully considered in their relative bearing on each other.

ACCORDING to modern theories, diabetes is supposed to depend, to a large extent, perhaps entirely, upon derangement of the vaso-motor mechanism of the liver. This point in the pathology of the disease has been the subject of a recent series of investigations by M. LAFFONT, which have been published in the *Gazette Médicale de Paris*. CLAUDE BERNARD, as is well known, showed that division of the cord between the seventh cervical and first dorsal vertebræ arrested the effects of the "diabetic puncture" of the floor of the fourth ventricle, and hence concluded that the path of the nervous influence was by the splanchnic branches of the sympathetic, and that the glycosuria is the result of an irritation, not of a paralysis, of the nerves, since the latter would not be removed by a second division of the path. M. LAFFONT has endeavoured to ascertain the truth of this opinion, by stimulating the first dorsal pair of nerves by faradisation, and observing the effect of this stimulation on the vessels of the liver. In the first series of experiments he opened the spinal canal, and divided the cord at two spots, isolating a segment corresponding to the first and second dorsal pairs. He next exposed the liver, and observed changes in its vascularity by the naked eye. The observations were made upon dogs. On irritation of the isolated segment of the cord, the liver was observed to present disseminated congestion, accompanied by a corresponding injection of the intestine, and turgidity of the spleen. The view that the morbid influence is irritative rather than paralytic is thus confirmed.

BERNARD also found that the stimulation of the central

extremities of the vagus increased the amount of sugar produced; while BEZOLD ascertained that similar stimulation caused, in curarised animals, a fall in intra-arterial pressure, which, LUDWIG and THIRY showed, was due to dilatation chiefly of the abdominal vessels. VULPIAN attributed this effect to the simultaneous stimulation of the central extremity of the depressor branch of the vagus. M. LAFFONT has endeavoured to ascertain whether this latter view is correct, and he found that intermitting stimulation for an hour of the central extremities of the depressor nerves, by means of a weak faradaic current, produced actual glycosuria, the sugar amounting to from twenty-five to forty-nine grammes per litre of urine. This fact had, indeed, been already ascertained by FILEHNE, who stated further that the faradisation of the central extremities of the pneumogastriacs themselves in the rabbit does not cause glycosuria. The latter fact is not corroborated by LAFFONT. He was able by such stimulation to cause a glycosuria amounting to from eight to seventeen grammes of glucose per litre, and believes that it is due to the asphyxia produced by this stimulation.

In another series of experiments it was found that painful stimulation of any mixed nerve, frequently repeated, caused glycosuria at the end of a certain time, amounting, in different animals, to from four to nine grammes of sugar per litre. Next, the effect of division of the first two or three pairs of dorsal nerves on the glycosuria resulting from puncture of the floor of the fourth ventricle was investigated in rabbits. Threads were placed around the roots of the first two dorsal pairs, and, the effect of the diabetic puncture having been ascertained, the nerves were torn through by means of the thread. The effect was that the sugar fell from twenty and forty grammes per litre to seven or twelve grammes. The effect of this operation on the vascular phenomena caused by stimulating the central portions of the pneumogastric or depressor nerves was then examined. It was ascertained by means of a cannula introduced into the carotid or crural artery. In the dog, the stimulation of the central extremities of the pneumogastriacs with a strong current caused always an enormous increase of pressure, while feeble stimulation produced, on the other hand, a considerable diminution of pressure. The roots of the first three or four dorsal nerves were then torn through, and after this the feeble stimulation, which had before caused a fall in the blood-pressure, produced a considerable rise. The result was the same in the rabbit, with the exception that a strong stimulation of the depressor nerves never caused an increase in the blood-pressure. Thus the separation of the dorsal nerves prevents the effect upon the circulation otherwise caused by the stimulation of the pneumogastric or depressor nerves.

What is the effect on the abdominal circulation of stimulating the peripheral extremities of the upper dorsal nerve roots? Since all the roots could not be simultaneously excited, the first pair only was stimulated, the animal being under the influence of curara. A fall in the blood-pressure resulted, not considerable in degree, because under the influence of curara there is already dilatation of the abdominal vessels. The pressure was estimated in the splenic artery, or in one of the branches of the mesenteric artery. It was thus ascertained that the stimulation of

these nerve roots by a weak faradaic current caused always a fall in the arterial pressure in the abdominal organs if the root is carefully isolated. The least extension of the current to the spinal cord itself caused an increase of pressure.

The conclusions drawn from these experiments confirm the view that the glycosuria which results from the stimulation of the central extremities of the pneumogastric nerves in the dog, the depressor nerves in the rabbit, and the sensory nerves generally, is the result of an impression conveyed to the bulbar vaso-dilator centre, the path from which is by the cervical cord, the first dorsal nerve roots, and the sympathetic and splanchnic nerves. It is conjectured to be by an action upon this centre that certain cardiac and general diseases may cause glycosuria. These effects, and those of the diabetic puncture, are prevented by the separation of the upper dorsal nerve roots, while the effect of stimulation of these divided roots shows that they contain dilator nerves for the vessels of the abdominal viscera.

WE have lately inserted several letters on the question of cheap methods of doctoring. We have not been able to give a place to all the letters; but those who defend low charges for professional services cannot complain that their side of the question has not had a fair hearing. We were the more anxious to give this, as the profession of late has been much scandalised at the bold way in which advice and medicines have been offered to the public, as if they were very cheap and valueless wares indeed. Those who are much condemned ought to have an opportunity of defence. Moreover, we confess to feeling that the problem of giving medical service to the poor on proper terms is one that is full of interest. The poor must have a doctor. They can do without lawyers, and perhaps even without clergy, but the great human art of medicine is in constant demand by all sorts and conditions of men. None of the experience yet collected is conclusive or satisfactory. The old gratuitous system has, to say the least, been abused; the club system applies chiefly to *men* the least exigent section of the community in a medical respect; the provident dispensary system is too systematic for large sections of the community, and even where it is adopted is exacting and not very profitable to medical men. We, therefore, are not disposed to dismiss with a hasty and contemptuous condemnation those who try to bring multitudes of people under legitimate medical treatment who would otherwise go to the chemist, or remain untreated, or run up medical bills without the power or the intention of paying them.

Our readers will judge for themselves how far such practitioners have made good their defence. Their letters are very interesting, very ingenious, and show considerable experience, and no little medical ability. They are evidently written by principals, who if they themselves could see patients in reasonable numbers, at reasonable charges, would be doing great service to the community. But a close inspection of their letters, and of such letters as that of "M.D.," will show that there are many gaps in their case, and many statements which would require very severe criticism before they could be accepted, and many others which tell against the system which they are adduced to support. Our correspondent, "L.R.C.P. Edin.," for ex-

ample, states that the shilling a week system does not injure other practitioners; and that the drug bill of a dispensary paying £500 a year does not exceed £70. This estimate is confirmed by "M.D. Lond.," who tells us that he sees sometimes over two hundred patients a day. This gentleman discusses the question—How is it that these cheap private dispensaries are often disreputably conducted? His answer to this is the difficulty of finding suitable men, which he defines as men of business capacity, honesty, punctuality, a little capital, and fond of work—such men, in fact, as make the assistant-physicians of out-patient departments of hospitals, *plus* considerable administrative talent into the bargain. To expect all this in one man, and to make the system depend on such a rare combination in one man, is to pronounce its failure and impracticability. We will not too closely criticise the fine estimates of the cost of drugs, though we do not think so lightly of the cost of providing and dispensing drugs in a proper and palatable form. Some of our correspondents do not hide their contempt of medicines. We do not share that feeling. Rich people have many ways of getting well, and restoring their strength. The poor are particularly dependent on good, sound, suitable medicines and advice, tendered by a man of good judgment. Can this be done by the ablest and strongest man if he has to see two hundred a day—or even one hundred a day? We think not. The work must be scamped. It is a very different thing from the case of the out-patient department. There the physician has students and clinical clerks and assistants at his elbow, to each of whom he can assign various duties; but even he is often jaded by seeing half the number twice a week.

What is likely to happen when such crowds throng the cheap dispensary, but that the principal will employ assistants—probably unqualified, as in the damaging case quoted by "M. D."—who may have both to see patients and dispense medicines—with what leisure, or care, or ability, we must leave our readers to imagine.

Finally, the gentlemen who have so ably defended charges that seem to us calculated to bring physician and medicine into contempt, have conspicuously avoided one feature of their system—the entire absence of any pretence of selecting cases or persons. To open doors at a given hour to see all and sundry persons for a shilling a week, is virtually to invite the patients of other medical men, and to offer an inducement to the mean and the thoughtless to get that for sixpence which they should pay five sixpences or five shillings for. It is therefore a direct way of underselling medical brethren. The system has its advantages. It procures ready money, and to judge from some ostentatious facts, a good deal of it. It shortens the undoubtedly trying period of a medical man's life, that in which he has to wait. But it does not hold high the principles by which physicians in all ages have commanded the respect of the public and of each other.

DR. GEORGE KING, superintendent of the Calcutta Botanical Gardens, has, we understand, been chosen by the Indian Government to discharge the duty of selecting a site on the Andaman islands for the experimental cultivation of the chinchona. Meanwhile the trees planted in Bengal are said to be paying handsomely, some 400,000 lb. of bark having been harvested.

Annotations.

"Ne quid nimis."

FOGS.

THE attention which is being directed to the subject of our London atmosphere will, it is to be hoped, bear some fruit, for there can be no doubt that the question is one of great importance, and that the present condition of the air we breathe is nothing short of a grave national calamity, and one which calls for the active interference of the Legislature. In a city, situated as London is, on the estuary of a great river, fogs must be expected, and all that we can hope to do is to prevent the foggy atmosphere from being fouled by smoke, and thus to reduce the evils and inconveniences to a minimum.

We will briefly epitomise the evils of our dirty London air. As regards health these evils are *acute* and *chronic*. The acute evils are shown by the returns of the Registrar-General. Last winter the death-rate was more than doubled chiefly by the increase of mortality from pulmonary disease. In 1873 the same alarming mortality occurred; and the smoke proved fatal also to a large number of the beasts exhibited at the Smithfield Show, no less than ninety-two of them having to be removed from the Agricultural Hall to be slaughtered at once, or "recovered," if possible, in the country. We need say nothing of "fog casualties," which are also to be reckoned among the acute evils, and serve to swell the death-rate.

The chronic evils attendant upon our atmosphere are, we believe, more serious, though attracting less attention, than the acute evils. The chief of these is the almost complete absence of sunlight for a great part of the winter. That sunlight is absolutely necessary for the proper development of both plants and animals, is a fact so generally accepted as to need no arguments from us. To what extent anæmia, rickets, and the general feebleness of the children of the London poor are attributable to want of light we cannot accurately determine, but that it plays an important part in the causation of many states of constitutional feebleness is universally admitted. On this account we felt constrained some years ago to recommend the removal of the Bluecoat School; for the Cimerian darkness of Newgate-street is not fitted for the development of young creatures who ought during their school life to double or treble their body weights. Our suggestion (which is soon to be carried out) would not have been necessary had London been blessed with a clear atmosphere. Some of the great endowed schools of London have already been removed to the country, others are to follow, and thus the citizens will be deprived, mainly by this foul atmosphere, of those educational advantages provided for them by benevolent ancestors. We remember once meeting a sporting gentleman who pooh-poohed these notions about sunlight and purity of atmosphere being necessary for the healthy development of the young; but when we asked him if he would like to keep a Derby favourite in a London mews and train it in Hyde-park, he altered his tone, and evidently did not approve of any blasphemous comparisons between mere babies and thoroughbred yearlings. In these days of competition, when every child is, willy nilly, entered for a race as soon as born, the question of a favourable situation for healthy development is doubly important.

Besides the absence of light there is the positive evil of the presence of artificial light during the greater part of the twenty-four hours, so that we are compelled to breathe air laden with the products of combustion, even during the daytime. If London blacks could be abolished, London ought to become a very favourite winter residence. It is one of the best drained, best sewered, best paved, and cleanest city in the

world; and having a temperature some degrees higher than the open country, and its resources for intellectual enjoyment being unrivalled, it ought to form, in winter, a focus of attraction to all classes. As it is, however, physicians are obliged to forbid patients to come to town in the winter if there is the slightest suspicion of lung disease, and are constrained either to keep them in the country or to send them abroad in search of fresh air and sunlight. It is recognised, also, that London is a bad place for convalescents, and that for complete recovery from illness a removal from town is absolutely necessary. The effect of this upon the value of house property, upon trade, and, lastly, upon the pockets of our own profession in London, we need not stop to inquire. The only wonder is that anybody not actually compelled will consent to live in a town where flowers cannot be made to grow, where sunlight is a rarity, where all we touch is smutty, and where the very statues in the streets succumb to the biting acidity of the atmosphere. To set off against all this positive evil there is the hypothetical antiseptic power of the smuts, which is said to be as inimical to disease germs as to other forms of life. Be this as it may, it is certain that we have our share of so-called zymotic diseases in London.

There is little doubt that the nuisance is extending. As the population increases chimneys increase also, and there are now, at least, as many chimneys as persons in this overgrown town. As the smut-producing area is being increased, it is obvious that the central parts of that area are certain to be overcast whenever the wind is much short of half a gale, no matter what may be its direction.

The evil being so great and so ruinous to the inhabitants, it behoves us to set to work seriously to remedy it; and we have no doubt that it only needs a little wise legislation in order to greatly mitigate, if not to entirely cure it. Suppose a law were passed simply disallowing a chimney to vomit forth blacks, what are the remedies to which we might have recourse? First, there is the employment of smokeless fuel, such as gas, coke, anthracite, peat, and wood. The rich would still be able to enjoy the luxury of an open fireplace without at the same time sending forth a shower of blacks from the chimney tops; and gas might certainly be used for all mere heating and cooking purposes. Possibly a supply of hydrogen might be forthcoming for heating purposes, which should be at least as economical as coal. It is needless to say that during the past few years great improvements have been made in stoves of all kinds. We now derive a far greater amount of available heat from a given quantity of fuel than formerly was the case, and a very small amount of pressure is needed to make the employment of such stoves universal. At present houses are built without a thought for their economical and efficient warming, and the dozens of houses which are finished every day in London and its neighbourhood have all the faults of construction observable in those which are two centuries old.

Something might at least be done to prevent the low chimneys of mews from sending their blacks directly into the windows of the drawing-rooms and bedrooms of the big houses adjoining them, and if no chimney of a furnace or fireplace in which coal or wood is consumed were allowed to be of a less height than, let us say, sixty or eighty feet, we should be relieved of some of the disadvantages of living in a land the wealth of which is largely dependent upon coal.

WHAT IS A COLD BATH?

THE season of the year when very many people who have experienced pleasure and advantage from a daily cold bath have to discontinue the practice is come. Months will elapse before the return of genial weather will allow of their indulgence in what may be termed man's natural stimulant. Among the young and robust there are a large

number who are able to bathe even in the depths of winter; the advantage of so doing is, however, questionable. But let it be once well understood what a cold bath really is, and the course by which we can avoid Scylla and Charybdis will be obvious. A cold bath is not necessarily a bath in water of the temperature of the atmosphere. A bath is truly and really cold when it produces a certain physiological effect—a slight momentary shock followed by pleasant and lasting reaction. These effects are for the majority of people most pleasantly obtained by bathing in water about 35° to 40° below the temperature of the body—the usual temperature of unheated water in June and July. Bearing this in mind we can enjoy our physiological “cold” bath as safely and pleasantly at Christmas as at Midsummer, and there is no necessity for the most timid or weakly to discontinue his morning tub because the summer weather is over. When the water sinks below a temperature of 60°, let it be heated to that point and then used, and we shall still have our “cold” bath, though of heated water. The daily stimulant effect of such a bath is so beneficial to the great majority of persons and is of such marked service in maintaining health, that it is very important to have it widely known that a cold bath may be taken all the year round provided cold is not mistaken to mean “at the temperature of the outer air.” To heat our bath during the winter months is too often thought to be unmanly, while in reality it is truly scientific, and to bathe in unheated water all the year round, whatever the temperature that water may be, is to prove oneself an ignorant slave of outward circumstances.

OUR MILITARY PRISONS.

IN the report on the discipline and management of the military prisons for the year 1879, recently presented to Parliament, the Inspector-General, Colonel Sir E. F. Ducane, R.E., says nothing whatever of the health of the prisoners. In the appendix, it is true, there are extracts from the reports of the medical officers of most of the prisons, the general tenour of which is that the state of health of the prisoners has been satisfactory. There is also a “return of sickness during 1879,” which enables us to test the accuracy of these reports, and which yields some remarkable results. During the year 1879 there were on the average 2170 soldiers constantly undergoing imprisonment in the United Kingdom. Of these 1180 were in civil prisons, 437 in military prisons, and 553 in the military division of Millbank Prison. The military prisons were six in number, including Millbank under that head, and it is to them only that the return of sickness applies. They were Millbank, Gosport, Glencorse (in Scotland), Cork, Dublin, and Limerick. The cases of sickness in them during the year amounted to 400 per 1000 of the average daily number of prisoners, the proportion constantly sick to 37·69 per 1000, and the average duration of the cases to 34·41 days. There is no column in the table for deaths. In the extract from the report of the medical officer at Millbank two are stated to have occurred in that prison; none are reported in the other prisons, but this may possibly have arisen from prisoners occasionally being sent to the military hospitals when seriously ill, whose deaths, if they occurred there, would not appear in the prison returns. The results above stated show the proportion of cases to have been scarcely half, but their duration double that which occurs among troops serving in the United Kingdom, and the average constantly sick to have been about 2½ per 1000 less than among the troops. It is probable that the lower ratio of cases is due to the men not being exposed to those causes of disease which arise from their dissipation or recklessness, while their long duration depends upon the care taken to prevent men escaping any part of their punishment for trifling causes. But we calculate the results for each of the prisons separately there will be

found to exist so striking a diversity as to require some explanation. This is clearly shown in the following table :—

	Ratio per 1000 of strength. Cases.	Constantly sick.	Average duration of cases.
Millbank..	238.9	41.39	63.24 days.
Gosport ...	700.0	42.27	22.56 "
Glencorse..	560.0	28.85	18.80 "
Cork	1280.4	30.79	8.75 "
Dublin	227.5	32.76	52.56 "
Limerick..	392.9	17.29	16.06 "

The enormously high proportion of cases at Cork, with the very short average duration, would lead to the supposition that too great facility existed there for getting upon the sick list for trifling causes, while the low ratio at Millbank and Dublin, coupled with the long average duration, would tend to show that great care was taken to prevent prisoners escaping any portion of their punishment for mere trifling ailments. The great range in the proportion of cases and in their duration would seem to call for a searching inquiry into the manner in which the different prisons are conducted, and the duties of the medical officers are discharged. As no information is given in the report as to the diseases which have prevailed among the prisoners, it is impossible to form any conjecture of the causes of the great differences which exist. We can only call attention to the subject in the hope that the Inspector-General and the military authorities may institute a searching inquiry with a view to determine how far these differences arise from preventable causes, and whether they may not in some instances depend upon inefficient or injudicious management. It is to be regretted that no information is given as to the sickness among the soldiers confined in the civil prisons, as a comparison of the health of the men under the two different systems might prove of practical value in ascertaining the relative merits and defects from a health point of view, as far as soldiers are concerned, of the civil and military prisons respectively.

AN EDISONIAN ANÆSTHETIC.

READERS of *Punch* will remember an amusing parody of Edison's mode of announcing his discoveries, in which the parturient mountain and muscicular abortion were illustrated, if we remember aright, by an elaborate description of a new life-restoring beverage, which proved to be an infusion of tea. Truth is stranger than fiction, or at least as remarkable, and the parody of the satirist was—unless the *English Mechanic* has hoaxed its readers and many other respectable journals—a true prophecy. Physicians have been blundering for some hundreds of years in attempts at the relief of pain by external applications, but it has been reserved for Mr. Edison to solve the problem by a stroke of genius! They have discovered that various substances, organic and inorganic, lessen sensibility and relieve pain, and have used them singly and in various combination, and will look with eagerness, not unmixed with misgivings, for the addition to their armamentum which Mr. Edison offers them. Their misgivings will not be misplaced. The inventor of the phonograph, and of the electric lamp of the future, gravely proposes as his latest invention to mix certain familiar anæsthetics together to make a new one. In the words of the *English Mechanic*, "Mr. Edison's idea is to use a compound (*sic*) of a number of the most powerful chemical substances which act anæsthetically, and which have no effect upon each other. The invention further consists in placing in such compound various menstrua (*sic*) for dissolving the substances, which menstrua shall have no chemical action on each other, or upon the substances beyond effecting their solution. The object of placing in one compound all of the most powerful chemicals which act anæsthetically is to ensure the action of one of them—that is to say, if one does not act, the other may. The ingredients which are used

are hydrate of chloral, chloroform, ether, nitrite of amyl, morphia, camphor, alcohol, oil of peppermint, salicylic acid, and oil of cloves." Such is the precious compound which Mr. Edison is alleged to have "invented." It is scarcely an exaggeration to say the discovery is on a par with that of a sportsman who should propose to load his gun, at one and the same time, with a bullet, small shot, and a tallow candle, so that the charge may be equally available whether his mark be a stag, a sparrow, or a deal board.

SURGEON-MAJOR HANNAH.

THE General Commanding the Allahabad Division has issued the following Brigade Order touching the death of Surgeon-Major Hannah, in the terrible landslip at Naini Tal: "It is with the deepest regret that the Brigadier-General Commanding has learnt that, in the very serious calamity which occurred at Naini Tal, owing to a landslip on the 18th instant, many valuable lives of officers, soldiers, and others, have been lost, and that among these, Captain Goodridge, of the 35th N. I., and Surgeon-Major Hannah, A. M. D., attached to B Brigade, 4th Battery, R. A., stationed at Allahabad, have perished. Brigadier-General Cobbe was unacquainted with Captain Goodridge, but he deplores his sudden and premature death. From personal knowledge, he can testify to the great loss sustained by the death of Surgeon-Major Hannah, whose unsparing exertions during the late cholera epidemic will still be fresh in the minds of many. He is sure that Dr. Hannah will be sincerely regretted by every officer and soldier who has had occasion to know him in his professional capacity, while many will lament the loss of a friend taken thus suddenly in the prime of life and usefulness."

CONVALESCENT HOME FOR SCARLET-FEVER PATIENTS.

WE are glad to learn that a scheme has been set on foot by Miss Mary Wardell for the establishment of a convalescent home for the reception of scarlet-fever patients. There is no disease which needs such careful tending during convalescence, but the period during which the patient is dangerous to others is so long, that it precludes the possibility of his being sent to any of the ordinary convalescent institutions. The establishment of such a home would not only be of undoubted use to the patients themselves, but, by preventing them from returning too early to their ordinary vocations, it would lessen the risk of infection to others. Miss Wardell's scheme is still in embryo, but we feel sure that it only needs to be ventilated in order that it may soon enter upon its real life and pursue a career of very great utility. Of moral support Miss Wardell has no lack. The heads of our own profession, and many leading members of the aristocracy and philanthropy concur in approving the scheme and wishing her God speed. The sinews of philanthropy, after all, however, is money, and we trust that many will be found to put their hands deep into their pockets enable a site to be purchased and a suitable house to be commenced upon it forthwith.

UNINFLAMMABLE TISSUES.

THE French Société d'Encouragement pour l'Industrie Nationale has awarded to M. Martin, of Paris, a prize of 1000 francs for his preparations for rendering wood and textile fabrics uninflammable. For wearing apparel, &c., a mixture of sulphate and carbonate of ammonia, boracic acid, borax, starch and water is used, and several other preparations for similar uses are described. All seem well adapted for their purpose, although no remarkable novelty can be observed in them.

We have repeatedly urged that the use of some such preparations in theatres should be made compulsory, and

cannot help regretting that the Lord Chamberlain, who exercises so paternal an authority over the dresses which actresses wear, should be unable or unwilling to compel their safety from fire. Frightful accidents happen from time to time on the stage from the neglect of precautions which are well known and inexpensive, and such accidents, affecting as they do the safety of the audience as well as of the performers, are a disgrace to our stage censorship.

ANTISEPTIC INFLATION.

MR. J. HOLDEN WEBB, of Melbourne, has recently published a paper in the *Australian Medical Journal* describing and advocating a new plan of rendering old sinuses and putrid abscess cavities aseptic. At first such cases were dealt with by injections of carbolic acid lotion; more recently Volkmann has introduced his sharp spoons, by means of which the unhealthy granulation tissue forming the walls of such passages and cavities can be removed, and inasmuch as there is good ground for believing that septic organisms not only exist in the putrid discharge but also infest the secreting walls of such cavities, this must be considered, and, indeed, has proved, a valuable adjunct to the simpler plan of injections only. In dealing with very large cavities, irregular and sacculated, such as are particularly met with in connexion with disease of the spine, it is obviously very difficult, if not impossible, to inject fluid so thoroughly that it shall penetrate into every corner and exert its germicide property on every part, and in these cases also the use of Volkmann's sharp spoons is necessarily limited within very narrow bounds. It was for such cases that Mr. Webb tried inflation with carbolised air, as being more likely to give success. His apparatus is simple. Into a Florence flask he puts some crystallised phenol, and through the cork, which fits tightly, he passes two glass tubes, one passing to the bottom of the flask, the other only just beyond the cork. These tubes are bent at right angles just above the cork. To the long tube a Richardson's bellows is fixed. When in use the flask is raised on a stand, the acid melted and heated by a spirit lamp, and air forced by the bellows through the acid in the flask, and by the shorter tube into the cavity to be inflated. All the force of the hand is used in the inflation, the cavities being tightly distended, and although it "often makes the patient drowsy for some hours afterwards, and sometimes renders the urine smoky," Mr. Webb has not met with any ill effects. Thymol inflation has been followed by disagreeable sickness. In his paper cases of old sinuses, spinal and other abscesses, submitted to this treatment are detailed, and it is stated that the results in correcting septicity of discharge, and therefore in checking suppuration, fever, and hectic, and hastening recovery, have been very satisfactory.

THE PATHOLOGICAL SOCIETY'S DEBATE.

THE debate on Rickets will be opened on Tuesday, Nov. 16th, by Dr. Hilton Fagge. It will assist the Secretaries of the Society if gentlemen who intend to speak will inform them of the fact, so that suitable arrangements may be made. The debate will of course be quite open, and no previous notice to the Secretaries is necessary before taking part in it. The subject is well chosen, the duty of opening the debate wisely allotted, and we may expect a valuable discussion.

THE HERTS CONVALESCENT HOME.

THE new building of this institution is to be opened under royal and noble auspices at St. Leonards on the 28th inst. It is gratifying to be assured that the institution will be governed by a managing committee, the constitution of which will be satisfactory to all parties. The existence of such a committee makes the institution a public one, and throws

on the public the pleasant and binding duty of supporting it. We do not quite understand the restriction implied in the title. Is it that only Hertfordshire men are to be allowed the pleasure of contributing, or that Hertfordshire patients only are to share and use the institution?

MANAGEMENT OF NATURAL LABOUR.

DR. J. W. SINGLETON, of Paducah, Ky., in a paper read before the Tri-State Medical Society on the Management of Natural Labour, argues strongly in favour of the use of the abdominal bandage before delivery as well as after, and of a dose of ergot of rye just before delivery. There is a tendency to what our American brethren call "hyfalutin" in Dr. Singleton's style of writing, but his strong advice in favour of the bandage and ergot may be recorded, the more so as he attributes to them the fact that, during twenty-five years' practice, he has never had a serious case of post-partum hæmorrhage. There is still to be found, or to be heard of, now and again a practitioner who does not apply a binder after delivery. This, we think, a great omission, and there is something to be said for having it placed before delivery, so as to exercise a little gentle pressure on the abdomen and uterus before delivery takes place.

HOSPITAL SUNDAY IN CUMBERLAND AND WESTMORELAND IN 1880.

THE sum of £1176 13s. 11d. has been obtained for the benefit of the five principal medical charities connected with the counties of Cumberland and Westmoreland in the present year, and the sum of £10,349 2s. 11d. in the eleven years since the fund was established. The names of the institutions which participate in the collections are as follows:—The Cumberland Infirmary, the Carlisle Dispensary, the Carlisle Fever Hospital, the Cumberland and Westmoreland Convalescent Institution, at Silloth, and the Whitehaven and West Cumberland Infirmary. Each charity has a medical representative on the committee of the fund.

THE Royal Free Hospital has, it is stated, become entitled to a moiety of the estate of the late William Birks Rhodes, valued at £78,000; the other half going to the National Life Boat Institution.

DR. AQUILLA SMITH has been re-elected for the ensuing year a representative of the College of Physicians in Ireland, on the General Medical Council.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hampstead (estimated population 45,500). — Dr. Edmund Gwynn, in making this, his first, annual report as medical officer of health for the parish of St. John, Hampstead, has injudiciously followed the course of adapting his report to the practice followed in other parochial reports for his district. His report refers to the twelve months ending March 25th, 1880—to a period, in fact, not comparable with the yearly period included almost invariably in reports of this kind throughout the kingdom, and more especially with the returns of the Registrar-General. The inconvenience of adopting this course is made sufficiently obvious in the report itself; as, for example, we find Dr. Gwynn using the Registrar-General's computed death-rate for England and Wales for 1879—that is, for the year ending in December; while he gives the death-rate for Hampstead for the twelve months ending the 31st March following, not even keeping

to the parochial year, the 25th! Again, in Table V. of his report, relating to the mortality from the principal zymotic diseases in Hampstead during the ten years 1870-79, Dr. Gwynn adopts the ordinary year, no guidance being given as to the distribution of the deaths in the parochial year followed in the report. Evidently much more is lost to Hampstead in the removal of the means of comparison of the vital statistics of the place with those of other places than is gained by adapting the form of the report to that of others with which it has nothing in common.

The birth-rate of Hampstead for the year ending the 31st of March, 1880, was 22.98 per 1000 inhabitants; the death-rate 13.07, or, deducting the deaths of non-residents, 12.4. The low birth-rate is attributed in part to the large proportion of persons well advanced in life among the inhabitants, and of domestic servants employed. The very low death-rate, notwithstanding that we are disposed to esteem Hampstead very highly as a healthy place of residence, suggests that the population may have been estimated at too high a number. Dr. Gwynn has, happily for his district, to make a very uneventful report. Since the closure of the small-pox hospital, no death from that disease has occurred in Hampstead, but this does not imply that the parish has been free from the disease during that period, for it appears that several cases occurred, two of which were sent to the Homerton hospital, and one to Highgate. The result of the cases so sent is not stated. Dr. Gwynn has a remark on water cisterns which deserves notice. He says: "Whilst the cisterns of our poorer neighbours are well looked after by the sanitary inspector, there is often considerable neglect on this head in houses of a better class." The following observations on new buildings are also worthy of attention: "The rapid strides that building has made during the past year in this parish deserve remark. The majority of the newly-erected houses are spacious and well-fitted with modern sanitary requirements. Additional accommodation is yet needed, both for the poor native to the place, and for those attracted hither by the building operations. To meet their requirements a class of cheap houses spring up, built often with inferior materials. Although the plans for their drainage have been submitted to, and approved by, the Vestry, yet bad workmanship, together with inferior fittings, soon give occasion for complaints, only too well-founded. The habits of the poor—washing, cooking, and living in the same room—rapidly lead to dirty walls and ceilings, which require the constant supervision of the sanitary inspector. Planned for the use of one family, they are not adapted for lodgings, the cooking appliances are inadequate, and the closet accommodation is often poor. The problem of providing fitting buildings for the poor is a difficult one to grapple with. The difficulty consists in supplying the accommodation for families whose bread-winner earns little more than 22s. per week. It is obvious that from three to four shillings per week for rent is all the strain such an income will bear, and this is the value of one small room in Hampstead. Overcrowding becomes, to a certain extent, inevitable. Whilst seeking to avoid pauperising the labouring man, it is for this class that relief must be sought. Hitherto it has been found that the tendency of charitable bodies, such as the Peabody Trustees, has been to draw down the better class of well-to-do work-people to the superior accommodation provided rather than to raise the lowly."

TYPHOID AT CHURCH COPPENHALL.

An "alarming" outbreak of typhoid fever is reported to have occurred at Church Coppenhall, near Crewe. Thirty cases were notified in a few days, and of these four had already died. The locality is stated to be entirely without sewerage, "slops" and surface drainage finding their way into the ditches and hollows by the roadside. The water-supply until very recently was derived wholly from shallow wells, or from surface ponds, and much of it was, and still is, necessarily greatly polluted. Within the last few weeks, however, a main has been carried to the place from the London and North-Western Railway Company's Water-works at Crewe, but as yet few of the inhabitants have taken a supply from thence. It is to be feared, moreover, that the high rates charged for the Company's water will interfere with any rapid extension of its use. The rector and surveyor have been diligently at work endeavouring to induce householders to take their water from the new source, and a house-to-house visitation has been made by them; but we are given to understand that until some

measures are taken to secure the sewerage of the village, there will be little hope of effective removal of the conditions upon which the outbreak seems to have depended.

SCARLET FEVER IN PADDINGTON.

It would appear as if the recent extensive prevalence of scarlet fever in Paddington was about to be shown to have originated from infected milk, and that the outbreak would closely parallel in the circumstances of its occurrence the outbreak of typhoid fever which occurred in Marylebone a few years ago, and which also was traced to infected milk. The suspected milk was derived from certain farms near Thame in Oxfordshire, and in two of them Dr. Stevenson, the medical officer of health for Paddington, on inspection has discovered numerous cases of scarlet fever, some in a state of convalescence, affecting the milkers among others. From farms in the same neighbourhood came, it will be remembered, the infected milk which caused the outbreak of typhoid fever in Marylebone. A writer in the *Globe* of Thursday states that the milk is no longer supplied from the Thames districts, where the cause of the late outbreak of scarlet fever has been traced.

A deputation of the Sanitary Committee of the Corporation of Leeds recently waited upon the Board of Guardians of the town with reference to dealing with cases of infectious disease. The Corporation, as sanitary authority, had been called upon to remove many cases to the House of Recovery (Fever Hospital), and it found considerable difficulty in discriminating those cases which should, as pauper cases, be dealt with by the Board of Guardians, and those, as non-paupers, which should be dealt with by the Corporation. The Sanitary Committee asked the assistance of the Board in removing the difficulty they felt, more especially as the Corporation had to pay a greater sum per week for the treatment of cases sent to hospital by them than the guardians. The clerk of the guardians pointed out that the law was precise as to the duties of the guardians in the matter, and it would not admit of the arrangement suggested by the deputation. Pauper cases must be dealt with by the relieving officers in the first place, and in an appointed way; whereas the sanitary authority could give sole attention to the necessities of the public health. Whereupon the spokesman of the deputation observed that, if the law stood in the way of such common agreement between the guardians and Corporation as the deputation had hoped to be possible on the subject, there was an end of the matter.

Dr. Goldie's report on the sanitary condition of Leeds for the month of September shows the lowest excess of births over deaths he has yet had to record. This is accounted for by the very high death-rate of the period, which was 27.9 per 1000 population, as compared with 18.2 for the corresponding period of 1879. The mortality amongst infants under one year was no less than 300.5 per 1000 born. Commenting on infectious diseases prevalent during the month, Dr. Goldie says he has found that by posting the infected districts with large precaution bills he has to a certain extent drawn public attention to the danger of exposing the infected amongst the healthy. Parents have become more circumspect both with regard to the treatment of the cases in their own families and to the precaution of avoiding needless contact with families already infected. "The whole secret of prevention," he adds, "lies in this and complete isolation." Dr. Goldie has some observations on the provision of infectious-disease hospital accommodation in Leeds, which show that the sanitary authority has by no means given the attention to this subject which would be anticipated from the authority of so important a town.

The outbreak of scarlet fever still appears to continue at Chesham. Considerable difficulties are experienced in inducing parents to send their children to the sanitary authority's hospital, and the want of tact displayed by the authority in the beginning of the outbreak impedes its efforts to deal effectually with the outbreak now.

A motion was submitted to the rural sanitary authority of Ware, on the 5th inst., to the effect that in the opinion of the board the medical officer of health for the rural sanitary authorities of Bishop's Stortford, Hertford, Ware, and Buntingford unions, and the Stortford urban sanitary authority, "cannot efficiently discharge the duties of his office unless he is restricted from engaging in private practice within the limits of his district." It was pointed out in

the course of the discussion which followed, that, by the terms of the motion, the holder of the office would not be prevented from entering upon private practice outside the limits of the district, and the motion was lost by nearly two votes to one.

A deputation of the Local Rights Association was received by the Metropolitan Board of Works at its meeting on the 15th inst., and, with reference to the action of the Board in regard to their clearances and to dwellings for the working classes, urged the serious injury suffered by working men from removal, and contended that the Board should seek power to erect dwellings for them at the lowest practicable rents.

At the last monthly meeting of the Whitby Local Board, Dr. Taylerson, the medical officer of health, stated that although there had been 4000 visitors in the town during the quarter, the death-rate had kept under 15.0 per 1000 population, and the general state of health of the place had been better than it had ever been before.

The metropolitan sanitary authorities appear to be taking up the question of mortuaries vigorously. Bethnal Green has just completed one, St. Giles-in-the-Fields has decided to erect one, and now St. Pancras is considering the propriety of building one.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The rate of English urban mortality continues satisfactorily low. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 5334 births and 3073 deaths were registered last week. The births exceeded by 149, while the deaths were 202 below the average weekly numbers during 1879. The deaths showed a decline of 44 from those returned in the previous week, and were equal to an annual rate of 21.4 per 1000, against 21.3 and 21.7 in the two preceding weeks. The lowest death-rates in the twenty towns last week were 15.4 in Bristol, 18.5 in Wolverhampton, 19.0 in Sheffield, 19.8 in Manchester, and 20.0 in London. The rates in the other towns ranged upwards to 25.5 in Sunderland, 26.7 in Oldham, 28.9 in Hull, 29.7 in Leicester, and 30.6 in Salford. The high rates in the five last-mentioned towns were mainly due to excessive zymotic fatality. During the thirteen weeks ending on 2nd inst., the death-rate in the twenty towns averaged 23.2 per 1000, against 23.8 and 18.3 in the corresponding periods of 1878 and 1879.

The deaths referred to the seven principal zymotic diseases, which had been 912, 657, and 617 in the three preceding weeks, further fell last week to 564; of these, 232 resulted from diarrhoea, 14 from scarlet fever, 75 from fever (principally enteric), and 56 from whooping-cough. The annual death-rate from these seven diseases averaged 3.9 per 1000 in the twenty towns, and ranged from 1.7 and 2.8 in Newcastle-upon-Tyne and Plymouth, to 7.0 and 8.7 in Sunderland and Salford. The death-rate from diarrhoea did not exceed 0.9 per 1000 in London, but ranged upwards to 3.3 in Leeds, 4.1 in Wolverhampton, and 4.2 in Salford. The deaths from scarlet fever corresponded with the number returned in the previous week, and showed the largest proportional fatality in Sunderland, Salford, Oldham, and Liverpool. Measles was somewhat prevalent in Leicester. The death-rate from enteric fever was excessive in Liverpool, Bradford, and Leeds. Small-pox caused six more deaths in London, but not one in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had been 105, 95, and 92 at the end of the three preceding weeks, further declined to 85 on Saturday last; 16 new cases were admitted to these hospitals during the week, against 24 and 14 in the two previous weeks. The Highgate Small-pox Hospital contained nine patients on Saturday last.

The deaths referred to diseases of the respiratory organs in London, which had steadily increased from 124 to 266 in the five preceding weeks, further rose to 273 last week, and exceeded the corrected weekly average by 31; 164 resulted from bronchitis, and 68 from pneumonia. The annual death-rate from lung diseases was equal to 3.9 in London, and 4.9 in Liverpool.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 22.4 per 1000, against 18.8 and 19.6 in the two preceding weeks; this rate exceeded by 1 per 1000 the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 19.1 and 20.4 in Paisley and Leith, to 25.3 and 27.4 in Perth and Edinburgh. The fatal cases of the seven principal zymotic diseases in the eight towns which had been 134 and 116 in the two preceding weeks, rose again to 135 last week; they included 52 which were referred to scarlet fever, 23 to fever, 20 to diarrhoea, 18 to diphtheria, 18 to whooping-cough, 4 to measles, and not one to small-pox. The annual death-rate from these seven diseases averaged 6.4 per 1000 in the eight towns, and exceeded the rate from the same diseases in the twenty English towns by 1.4 per 1000. The zymotic death-rate in the eight Scotch towns ranged from 1.5 and 1.9 in Aberdeen and Perth, to 6.2 and 8.8 in Leith and Edinburgh; the high death-rates in the two latter towns were due to scarlet fever fatality. The fatal cases of scarlet fever in the eight towns, which had been 45, 33, and 30 in the three preceding weeks, rose to 52 last week, and included 23 in Glasgow, 22 in Edinburgh, and 5 in Leith. The 23 deaths referred to fever (including typhus and enteric, or typhoid) also showed a marked increase upon recent weekly numbers; 15 occurred in Glasgow and 5 in Edinburgh, showing in each case an exceptionally high rate of fatality. The 20 deaths from diarrhoea showed a further marked decline from the numbers in the four previous weeks, which had decreased from 69 to 46; the largest proportional fatality from this disease occurred last week in Edinburgh and Dundee. The deaths attributed to acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy) rose to 98 in the eight towns last week, from 76 and 66 in the two preceding weeks; the annual death-rate from these diseases last week was equal to 4.0 per 1000 in the eight Scotch towns, against 3.5 in London.

HEALTH OF DUBLIN.

A further slight decline from the recent excessive rate of mortality occurred last week in Dublin. The annual death-rate in the city has slowly but steadily decreased in the past five weeks from 39.3 to 33.0. During the thirteen weeks which ended on Saturday, 2nd inst., the death-rate in the city averaged, however, no less than 34.6 per 1000, against 21.3 in London, and 21.8 in Edinburgh. The 199 deaths in Dublin last week were 2 less than those returned in the previous week, and included 50, or 25 per cent., which were referred to the seven principal zymotic diseases, showing a further decline of 2 from recent weekly numbers; 14 resulted from diarrhoea, 10 from fever (including typhus and enteric), 9 from scarlet fever, 8 from whooping-cough, 4 from small-pox, 3 from measles, and 2 from diphtheria. The annual death-rate from these diseases was equal to 8.5 per 1000 in Dublin, whereas it did not exceed 3.0 in London, and was 8.8 in Edinburgh. The fatal cases of diarrhoea, which had been 44, 33, and 22 in the three previous weeks, further declined to 14 last week, but were equal to an annual rate of 2.3 per 1000, whereas in London the rate from diarrhoea did not exceed 0.9. The 10 deaths referred to fever showed an increase of 3 upon those in the previous week. The deaths from scarlet fever and diphtheria were also more numerous, whereas those from measles and whooping-cough showed a decline. The 4 fatal cases of small-pox exceeded the number returned in any week since the middle of August. The rate of infant mortality showed a further slight decline last week, but the proportion of deaths under one year during the thirteen weeks of last quarter were equal to 252 per 1000 of the births registered, while in London the proportion during the same period did not exceed 164 per 1000.

SUMMER DIARRHOEA IN 1880.

The prevalence and fatality of infantile diarrhoea have been exceptionally severe among the urban population of England during the past summer. In the twenty large English towns dealt with in the Registrar-General's Weekly Return, no less than 8292 deaths were referred to diarrhoea during the thirteen weeks ending 2nd inst., against 7675 and 2245 in the corresponding periods of 1878 and 1879. These deaths were equal to an annual rate of 4.4 per 1000 of the estimated population of the twenty towns. The diarrhoea

rate was 3·3 per 1000 in London, and averaged 5·6 in the nineteen large provincial towns. The lowest death-rates from diarrhoea last quarter in the provincial towns were 2·4 in Bristol, 3·3 in Oldham, and 3·8 both in Portsmouth and Plymouth; the rates in the other towns ranged upwards to 6·8 in Norwich, 7·8 in Hull, 8·4 in Salford, and 10·6 in Leicester. Thus, notwithstanding the marked general increase in the fatality of diarrhoea last quarter, the same towns are to be found at the top and bottom of the list as in former years, when the mortality from this cause was much lighter. Year after year, the least fatality of diarrhoea occurs in Bristol and Oldham, and the greatest in Hull, Salford, and Leicester. The average fatality of diarrhoea in the twenty towns last quarter showed but a slight increase upon that which prevailed in the corresponding period of 1878, but the relative rates in the several towns in the two summers varied considerably. In Hull, for instance, the rate last quarter was 7·8 per 1000, and 2·4 lower than that which prevailed in the summer of 1878; in Salford and Leicester, however, the rates showed last quarter an excess of 2·0 and 1·6 per 1000 respectively. The fatality of other diseases of the zymotic class were last quarter below the average in the large English towns, but in consequence of the exceptional mortality from diarrhoea, the annual death-rate from all causes in the twenty large towns averaged 23·2 per 1000 of the estimated population, against 20·4, 23·7, and 18·3 in the three preceding corresponding quarters. Assuming that the rate of mortality in these twenty towns bore the same relation to the rate of mortality in the whole of England and Wales which usually prevails in the third quarter of the year, we may estimate the death-rate last quarter in the entire country at nearly 21·0 per 1000, which would exceed the rates which have prevailed in any corresponding quarter since 1870 and 1871, when they were 22·0 and 21·1 per 1000 respectively. Until the publication of the Registrar-General's Quarterly Return we shall have no authentic figures showing the total cost of the late hot summer, especially to infant life, but from local reports upon the health of many urban sanitary districts there is good reason to believe that a marked excess prevailed throughout a large proportion of the manufacturing and mining populations of the Midland and Northern counties.

RATES OF MORTALITY IN EUROPEAN CITIES.

The rates of mortality in most foreign cities compare most unfavourably with those that prevail in the large towns of the United Kingdom. In the second quarter of this year the annual rate of mortality in twenty of the largest English towns, having an aggregate population of about seven and a half millions of persons, averaged only 20·4 per 1000; whereas in twenty European cities the rate averaged 32·4. This remarkable excess in the death-rate signifies that the mortality in the European cities was 59 per cent. higher than that in the English cities, or, in other words, in equal numbers living, 159 died in the foreign cities to each 100 in the English cities. This marked excess in the death-rate in foreign cities is pretty constant, but the rates last quarter showed more than the usually wide variations; they ranged from 19·9 and 21·3 in Christiana and the Hague, to 39·8 in Buda Pesth, 40·5 in Munich, and 54·8 in St. Petersburg. In Madrid the rate was equal to 37·3, and in Monaco 40·5. In three of the largest Italian cities high rates also prevailed, 30·2 in Milan, 32·2 in Naples, and 33·7 in Rome. In Paris the rate was but slightly lower, it was 29·9 against but 19·4 in London, the excess being in a great measure due to the fatality of zymotic disease; the deaths in the three months included 1043 from diarrhoeal diseases, 691 from small-pox, 595 from diphtheria, 485 from typhoid fever, 343 from measles, 127 from whooping-cough, and 110 from scarlet fever. The death-rate last quarter was equal to 35·8 in Bucharest, 39·7 in Odessa, and 40·6 in Lemberg. The interchange of mortality statistics between different cities will doubtless tend to call attention abroad to the high death-rates which are still continually reported, and we note with hopeful interest that most of the European and American States now publish side by side with their own local mortality statistics, a selection of those reported in all parts of the civilised globe. With the rapidly increasing facilities for intercommunication no nation can now afford to regard with indifference, if only on selfish grounds, sanitary neglect among the peoples with whom they hold constant intercourse.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

INFECTIOUS-DISEASE HOSPITALS.

The account given by Sir John Rose Cormack, M.D., at the Social Science Congress, of Dr. Bertillon's inquiry into the presumed influence exercised by the small-pox hospitals of Paris on the prevalence of that disease in their immediate neighbourhood does not, it appears to us, call for any modification of the opinion we expressed when the results of the inquiry were first published. Granting that Dr. Bertillon was right in the statistical evidence he gave of a greater prevalence of small-pox in the neighbourhood of the hospitals than elsewhere in Paris, his inference that this prevalence depended upon some general diffusion of small-pox contagion from the hospital building, and not upon the more familiarly known ways of the spread of small-pox, seemed to us to be almost wholly gratuitous, and had no more claim to a scientific conclusion than the popular opinion formed to the same effect by a section of our general population with regard to the influence of the metropolitan small-pox hospitals on their neighbourhood. We regret to find Dr. Cormack so far adopting Dr. Bertillon's inference as to use the phrases, "a poison-charged drift of epithelial scales," "the epithelial drift," &c.; and we think there must be a misprint in the reporter's statement of the proceedings of the Congress, when Dr. Cormack is represented as stating, in effect, that the poisonous epithelial drift may extend a quarter of a mile and then prove infective. Dr. Cormack's statements did not carry conviction to those of his hearers most capable of judging of the question, as, for example, Sir Robert Christison, Dr. Littlejohn, Dr. Semple, Dr. Wallace, Dr. Andrew Wood, Dr. Acland, &c. Dr. Acland's observations to the effect that the spread of the disease round the Paris hospitals probably arose from the fact of their being ill-managed, was of greater importance than Dr. Cormack perhaps apprehended. At any rate, it is owing to the fact that Dr. Bertillon's remarks and inferences from his inquiry as to the dissemination fail to indicate that due care was given by him to eliminate the ordinary modes in which the contagion of small-pox spreads before he called to his aid the theory of a "poisonous epithelial drift," to use Dr. Cormack's words, that we have been unable to repose confidence in that theory.

CITIZENSHIP IN SANITARY WORK.

Hitherto voluntary associations for watching the operations of sanitary authorities within their districts, seeing that they duly exercise the functions entrusted to them by the law for the benefit of the communities under their charge, and cultivating a healthy opinion among the persons concerned in regard to those functions, have, as a rule, as in the case of the Tottenham Sanitary Association, been confined to the wealthier sections of society. We remark, with no little gratification, the extension of associations of this sort among the sections of society who do not claim to be wealthy, and who, we infer, include many artisans and others of the so-called labouring classes. Our attention has been attracted by the proceedings of a meeting called together by the Local Rights Association for Promoting Rental and Sanitary Reform, and which appears to give much attention to the sanitary condition of houses and places, with a view to exercising such influence as the Association possesses in procuring improvement where needed. One remark in the report of the proceedings somewhat grates upon our feelings. It is to the effect that "the Association would continue to point out to their wealthy neighbours the danger of contagion arising from these (insanitary) causes. We venture to think that the efforts of the Association would be much more profitably directed, both as regards their wealthier neighbours and the public generally, if they were concentrated upon the sanitary authorities with a view of keeping them up to the mark in the performance of their duties. In doing this they would much more effectively reach neglectful individuals of the wealthier classes than by direct appeal to them. Moreover, we should like to see this Association, itself an indication of a move in this direction, if we err not, giving special attention to the cultivation of sounder notions of healthy house-requirements among artisans and other labouring classes. The curse of so-called "jerry-building" which has fallen upon the outskirts of the metropolis, the suburbs, and wherever building has sprung

up largely in the land, will never wholly cease unless house occupiers themselves are enlisted against it. So long as jerry-builders can find persons who will accept *their* notions of what constitutes a building and the health requirements thereof, so long this class of builders will continue, and be able to set the most active authority at defiance. There are abundant indications that dwellings, particularly cottage dwellings, improve in structure and arrangement with the improved requirements of occupiers, and this is a cardinal bit of experience which sanitary reform associations should work upon.

OUTBREAK OF TYPHOID FEVER IN CORNWALL.

The village of Newlyn East, a few miles from Truro, and near the north coast of Cornwall, is alleged to be the scene of an alarming outbreak of typhoid fever. Out of a population of about 1600, the large proportion of 80, mostly adults, are said to be stricken with typhoid. The medical officer of health believes the origin of the fever to be due to the drinking of water polluted by sewage matter, and that its rapid spread is chiefly attributable to overcrowding and defective sewerage. The village is exceptionally well situated, as it stands upon high ground and is swept by the Atlantic breezes. Six years ago, when the population was about 700, there was a similar epidemic in the village, eighty persons being attacked, sixty lying ill at the same time. Mr. Chambre Vigurs then fought the battle single-handed, and had only five deaths. On the present occasion he estimates that not less than 100 persons have been affected. The worst is now believed to be past. Mr. Edlin, of Plymouth, has lent Mr. Vigurs some assistance. The sanitary authorities of St. Colomb have now locked up the pump which supplied the supposed source of the infection. This might have been done earlier, as pure water can be obtained within the distance of half a mile. Two trained nurses from the South Devon Hospital are now on the spot. The publicity given to the matter by the *Western Morning News* has done good service.

The children at the district schools at Brentwood have been suffering rather extensively from ophthalmia, though the affection is not of a serious type, and the majority of the patients are now convalescent. The disease made its appearance in July last, and spread rapidly for a time. Out of a total of 660 children, 138 are now under treatment. Of these, about twelve are confined to the wards with more or less severe complications. We understand that, at the request of the managers, Mr. Nettleship has visited the schools and consulted with the medical officer, Mr. Albert W. Wallis, and that a report has been submitted on the subject.

A memorial has been presented to the Prime Minister by the Corporation of St. Ives, Huntingdonshire, representing the serious injury to which their borough and district are exposed, in property and health, by the frequent floods of the river Ouse, owing to the impediments interposed to the free flow of the river in its course. The memorialists pray that some measure may be promoted in Parliament which shall enable them to remove these impediments.

A gentleman writing to the *Liverpool Daily Post*, in the hope of directing attention to the advantages which families may derive from the use of infectious disease hospitals, gives interesting experiences in his own family from the use of the London Fever Hospital, and the Netherfield Institution for Infectious Diseases, Everton, Liverpool. It would be well if this gentleman's example were more largely followed.

We referred a short time ago to the advantages, in a public-health point of view, claimed for foot-paths constructed of wood. But equal advantages are claimed, we find, for foot-paths constructed of brick, and the advocates of brick have this in their favour, that they can indicate examples of this sort of foot-path in confirmation of their statements, as, for example, at Brighton.

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—The annual meeting of this Association was held at Sheffield in the Mayor's parlour. Papers were read by Dr. Hime, medical officer of health, Sheffield, on "The recent Outbreak of Diarrhoea at Sheffield," and by Dr. Drew of Chapeltown on "Sanitation in Utopia." A number of objects of special interest to medical officers of health were on view, and the proceedings terminated with a social meeting at the Wharnccliffe Hotel.

REPORT OF THE LOCAL GOVERNMENT BOARD.

I.

THE public-health portion of the Ninth Annual Report of the Local Government Board may, for our purpose, be conveniently divided into two parts—the one relating more particularly to sanitary work, the other to the operation of the Sale of Food and Drugs Act, 1875, which is given considerable prominence in the present report. We shall give attention to the sanitary work first.

During the financial year ending the 25th of March, 1879, the expenditure of the urban sanitary authorities of England and Wales was £18,663,757, and of the rural sanitary authorities £445,517. At the same date the outstanding loans of the urban sanitary authorities amounted to £56,591,080, and those of the rural sanitary authorities to £642,617. The aggregate rateable value of the urban sanitary districts at the date in question was £49,753,326. The greater portion of this indebtedness of sanitary authorities has been authorised by Parliament, but £18,824,168 of the sum has been sanctioned by the Local Government Board under the Public Health Act. Of this eighteen millions, £14,937,310 was sanctioned for sanitary improvements in urban districts other than schemes of improvement under the Artisans and Labourers' Dwellings Improvement Act, 1875; £1,176,045 for sanitary improvements in rural sanitary districts; £1,840,979 under the Artisans and Labourers' Dwellings Improvement Act, 1875; and £444,000 for sewerage works undertaken by joint sewerage boards. In the course of the year to which the report refers loans were sanctioned to urban sanitary authorities of £1,088,819 for sewerage and sewage disposal, and of £293,880 for water-supply; and to rural sanitary authorities of £191,097 for sewerage and sewage disposal, and £75,473 for water-supply.

The further experience of the Local Government Board as to the appointment of medical officers of health has led them more strongly to deprecate the appointment for small districts. They hold it inexpedient to employ district medical officers as medical officers of health, each acting within the area assigned to him as poor-law medical officer, and have been advising sanitary authorities, as opportunities have occurred, either to combine with adjoining sanitary authorities in a joint appointment for a considerable area, or, where that was impracticable, of appointing one medical officer of health only for the district within the jurisdiction of the authority, and in the latter case, of selecting for the office a medical practitioner free from the calls upon his time entailed by the performance of duties under the Poor-laws. The efforts of the Board appear to have been successful with sanitary authorities in this direction, and we may assume that the policy of the Board is now definitely settled in this matter.

The report refers to the loss sustained by the Board and the public service by the resignation (from failing health, soon followed by the death) of Dr. Seaton, and justly adds, "it is worthy of especial record that the organisation of the present successful system of public vaccination in this country is in great part due to his labours."

With regard to public vaccination, the report gives the completed returns of the vaccination officers for the year 1877. These, in the opinion of the Board, afford conclusive evidence of the efficiency with which, on the whole, the machinery established by the Vaccination Acts of 1867 and 1871 is working. Of 887,947 children, whose births were returned by the several vaccination officers of England and Wales as having been registered in 1877, more than 86 per cent. had at the time of closing the returns been registered as successfully vaccinated, nearly 9 per cent. as having died early and unvaccinated, and a minute fraction (0.13 per cent.) as having contracted small-pox without being vaccinated. A further small proportion (about 0.1 per cent.) were certified as "insusceptible of vaccination" in consequence of the operation having been three times performed without success; and in these cases the parents would be exempted from any further liability to penalty under the Vaccination Acts, although the children would be as liable to take small-pox as if no attempt had been made to vaccinate them. The returns further record cases amounting

to 0.75 per cent. of the whole, in which vaccination was temporarily postponed on account of the children's state of health. The proportion of children not coming within the above categories amounts to about 3.8 per cent. of the whole, the large majority being cases which, on account of the removal of the parents after the registrations of the births, the vaccination officers were unable to trace. No doubt, it is observed, such cases are especially numerous in years when, as in 1877-78, trade is bad, and there is much movement of labourers from place to place, sometimes in search of work, sometimes in search of cheaper quarters.

"It thus appears," the report continues, "that of the entire number of children born, only about $4\frac{1}{2}$ per cent. remain unaccounted for as regards vaccination in the returns. This proportion is larger by a small fraction than that of the children similarly unaccounted for in 1876, but is smaller than in previous returns, the percentage in the six years 1872-77 being 5.1, 4.8, 4.8, 4.7, 4.3, and 4.5 respectively. Making allowance for a not inconsiderable number of cases in which children have been vaccinated, although vaccination has not been certified, or the certificate has not been registered, and for those in which vaccination, postponed at the times when the returns were made up, has been subsequently performed, we may safely assume that the proportion of children born during these six years and now living without protection against small-pox is considerably less than 4 per cent."

The district in which the largest proportion of children escape vaccination is the metropolis. This is attributed chiefly to the migratory habits of certain classes of the population. The number of children who escape yearly from vaccination in London, or of whom there is no proof of vaccination, is stated to be about 9000, and so far as they really are unvaccinated they constitute a serious danger and widen the field of small-pox.

The awards given to public vaccinators in recognition of excellence of work done and careful observance of the instructions and regulations on the subject amounted to £16,906 17s. 4d. The applications to the National Vaccine Establishment for supplies of vaccine lymph during the year were 9410, and to meet them 36,633 charges of lymph were issued. The question of "animal vaccination" was under the consideration of the Board, but since the period to which this report refers the Board has determined upon certain measures with regard to this subject which render further allusion to it here unnecessary. Numerous inquiries were undertaken by the medical department of the Board with reference to outbreaks of disease and other sanitary matters, more particulars as to which will be here deferred until the special report of that department appears.

The number of annual reports sent by medical officers of health to the Board, in accordance with their instructions, during the year amounted to no less than 1403. The reports, it appears, present great diversity, but on the whole, the Board says, they exhibit progress from year to year, in correctly appreciating the questions with which the medical officer of health has to deal.

An inquiry has been instituted (or rather return called for) by the Board relating to the sanitary condition of the various districts, which have been the subject of special inspection by their medical inspectors since 1871. The report of the inquiry (or return) will be presented to Parliament, and will be looked for with much interest.

The Board has received several petitions from local authorities in favour of a general compulsory enactment that all householders, or all medical practitioners, should notify to the sanitary authority the outbreak of infectious disease. The Board, however, holds that further experience is required of the working of such schemes on the subject as exist under local Acts, before venturing to introduce a general measure. The Board, however, thinks it may be necessary to strengthen the hands of sanitary authorities with reference to the closing of schools on account of local epidemics of infectious disease.

Numerous other subjects touching sanitary administration enter into the report, for which, however, we must refer to the report itself.

On the 11th inst. a bust of Lord Provost Boyd was presented to the Royal Infirmary of Edinburgh by Sir Robert Christison. An inscription on the pedestal of the bust states that the erection of the new Royal Infirmary was due to the exertions of Lord Provost Boyd.

THE SERVICES.

THE AFGHAN WAR—KANDAHAR.

WE have received a letter from a correspondent with the Kandahar Army giving us some particulars of the force in occupation since the disaster of the 27th July. He describes the time as having been a most anxious one, not so much on account of scarcity of provisions or water as the intense heat of the weather, added to the confined space occupied by the garrison with the numbers of native followers, horses, and transport animals. In food the chief want was vegetables, of which there were none to be had, except some preserved cases fortunately stored by the Commissariat before the siege began. There was a fair supply of lime-juice, and this was issued to the troops daily as long as it lasted. Scurvy did not actually appear during the time the garrison was shut up, but a good number of cases were developing a scorbutic taint. The sickness up to the time of relief by General Roberts was not heavy, but the Bengal Division brought in no less than 860 sick; of these only 240 were Europeans, the rest native troops and followers. The cases were chiefly malarial and sun fevers, diarrhoea, and general debility, induced by the long marches, privations, and exposure. Surgeon-Major Preston, who was wounded in the arm and through the loins at the action of Maiwand when in medical charge of the 66th Regiment, left for India with a convoy of sick on the 7th September, and was doing well. At the sortie of the 16th August the medical officers and subordinates were most assiduous and zealous in their efforts to dress and bring in the wounded. Surgeon-Majors Giraud, Keith, Arnott, and Kelsall were with the attacking party. One hospital assistant and five doolie bearers were killed while carrying in wounded men; ten doolie bearers wounded. Great praise is given to these native bearers for their pluck and steadiness; they were often under hot fire, but showed no sign of disobeying orders, even at imminent risk of their lives. It was decided by Dr. Hanbury, the Principal Medical Officer of General Roberts's force, that a section of the Field Hospital should accompany each brigade into action on the morning of Sept. 1st, when the General determined to attack Ayoo Khan. Stretcher parties in charge of medical officers and subordinates were formed to convey the wounded from the field to the dressing stations and on to the Field Hospitals. As on the 16th, they did their work admirably, calling forth loud encomiums from the General and his staff. The total killed and wounded in this action was 237; the latter were comfortably housed in European privates' tents—six beds to a tent, instead of the regulated number of eighteen. The native sick were also amply provided for and attended to. On the march from Cabul to Kandahar only two Europeans died—one from dysentery, the other committed suicide. Of the Sepoys only seven died, and of the native followers twenty-one succumbed during the journey—a total that must be considered remarkably small when the arduous and trying nature of the march is remembered. That the medical officers did their duty with a will is proved by the fact that not one was ever absent from duty a single hour from Cabul to Kandahar—a fact of which their Surgeon-General is justly proud.

THE MEDICAL OFFICERS' MESS, ALDERSHOT.

General Sir Daniel Lysons and staff dined with the officers of the Army Medical Department on Wednesday, the 13th, in their new mess-room in the South Camp. By the kind permission of the officers of the 7th Dragoon Guards, the band of the regiment attended during dinner.

MEDICAL OFFICERS SERVING WITH THE KURAM FORCE.

To the Editor of THE LANCET.

SIR,—In your number of the 14th August, you give lists of the medical officers employed in Afghanistan. But your correspondent has only given the names of the Army Medical Department; leaving out all those of the Indian Medical Service, which in this force form half the medical staff and in the other divisions a much larger proportion, I believe.

I enclose a correct list of the Kuram Force Staff (Medical).
The Khyber line Divisions are now broken up.

Yours faithfully,

A. F. DALE,

Deputy Surgeon-General, P. M. O., Kuram Force.
Kuram, Sept. 22, 1880.

Deputy Surgeon-General A. J. Dale—Principal Medical Officer.

Army Medical Department.

Surge-Major T. Wright, European Base Hospital.
" W. O'Halloran in medical charge E-3 R. A. Kohat.
" R. Jackson " 2-8 Regt.
" J. J. O'Reilly " Depôt Hospital, Thall.
" T. W. Patterson " 1-8 R. A.
" W. M. Harman " 85th K. L. I.
Surgeons W. Donovan, doing duty with Base Hospital.
" R. H. Quill, in medical charge C-4 R. A.
" J. C. Dorman " Depôt Hospital, Kuram.
" J. Boulger, doing duty Depôt Hospital, Thall.
" P. H. Johnstone doing duty with Base Hospital.
" P. G. Jeners " Depot Hospital, Kohat.

Indian Medical Department.

Surge-Major G. Griffith, in medical charge 18 Bengal Cavalry.
" H. Compique, Deoli Irregular Force.
Surgeons W. N. Keefer in medical charge Native Base Hospital.
" J. E. C. Ferris, 1st Bengal Cavalry.
" W. E. Griffiths, in medical charge 20th Punjab Infantry.
" J. Crofts, in officiating medical charge 21st P.N.I.
" S. F. Bigger " 13th N.I.
" G. M. Nixon " 5th N.L.I.
" G. W. P. Dennys " 13th B. Lancers.
" S. C. Sarkies " 29th P.N.I.

Deputy Surgeon H. Kendall, who was promoted to the rank of Surgeon-General in last Saturday's *Gazette*, remains at Chatham as Principal Medical Officer of that district until he is retired on full pay, in January next.

ARMY MEDICAL DEPARTMENT.—Deputy Surgeon-General Henry Kendall, M.D., to be Surgeon-General, vice H. G. Gordon, M.D., granted retired pay; Brigade Surgeon John Ogilvy, M.D., to be Deputy Surgeon-General, vice H. Kendall, M.D.; Surgeon-Major William Skeen, M.D., to be Brigade-Surgeon, vice J. Ogilvy, M.D.; Surgeon-Major Emil Becher, M.D., is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major Thomas Allen Thornhill, M.B., is granted retired pay, with the honorary rank of Brigade-Surgeon; Surgeon-Major Francis Patrick Staples has retired upon temporary half-pay; Surgeon-Major Alexander Johnston, M.D., from half-pay, to be Surgeon-Major. The undermentioned Surgeons to be Surgeons-Major:—Alexander Haldane Stokes, M.B.; George Roderick Triphook, M.B.; James Scanlan, M.B.; George Corry; Francis Arthur Davy, M.D.; Alexander William Duke, M.D.; Robert Mark Bradford; Henry Stannard; Richard Dawson Bennett; Thomas Faris, M.B.; and Hugh Brady White.

VOLUNTEERS.—1st Norfolk (Artillery) Corps: William Mallam Vores, M.B., to be Acting Surgeon; dated Oct. 20th, 1880. 1st Buckinghamshire (Rifle) Corps: Cadwallader Brooke Wolseley, M.D., to be Acting Surgeon; dated Oct. 20th, 1880. 1st Worcestershire Corps: Honorary Assistant Surgeon Cecil Webster resigns his commission; dated Oct. 20th, 1880. 10th Lancashire Corps: John Murray, M.B., to be Acting Surgeon; dated Oct. 20th, 1880.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Orders in Council of Feb. 22nd, 1870, and Feb. 4th, 1875, Staff-Surgeon Alexander Crosbie, M.D., has been placed on the Retired List of his rank from the 8th inst.

Royal Naval Artillery Volunteers (London Brigade).—Arthur Price, M.R.C.S., to be Surgeon.

Surgeon J. A. Langdon has been appointed to the *Firefly*.

Correspondence.

"Audi alteram partem."

ON THE IMMEDIATE TREATMENT OF STRICTURE OF THE URETHRA.

To the Editor of THE LANCET.

SIR,—In my letter to you of Oct. 2nd, I omitted to refer to Mr. Holt's second note, in which he stated that there was a false passage in one of the fatal cases at King's College Hospital. As I mentioned that Mr. Henry Smith had had a death, and as it was to his case that Mr. Holt's remark applied, I think it only just to Mr. Smith to state that the false passage existed months before he even saw the patient, and had apparently nothing to do with the fatal result. If Mr. Holt had honoured the meeting at Cambridge with his presence, and stated, as he has done in his note, that he had been fortunate enough not to have had a fatal case in private, I should have asked him for information as to certain cases about which it is possible I might have been misinformed. Much good will come out of the discussion which has taken place in your columns. It was not known at the meeting that Mr. Christopher Heath had had five deaths, for, although that gentleman had published successful cases of the operation, *in extenso*, in THE LANCET, he had not enlightened the profession with the details of his fatal ones. My remark as to how few of the deaths had been published was based on a list I had with me at the meeting of upwards of thirty cases terminating fatally, which had occurred to different surgeons in this country, of which I had been accidentally informed by various members of our profession. In reply to Mr. Harrison, I would say that I am not aware that any advocate of internal urethrotomy has ever asserted of it, as Mr. Holt has done of rupture, that it was "free from every danger immediate or remote." I have yet to learn that such an affirmation can be made of any operation on the urinary organs: "A scratch in the urethra may cause death" (Gouley). As Mr. Macnamara has omitted to specify what were the "unsupported" charges to which he refers, I am unable to notice his letter. The advocates of internal urethrotomy are to be congratulated on Dr. Lyster's accession to their ranks. His example is just another illustration of what is to be seen all over the world of surgeons abandoning rupture and taking to cutting. If anyone can show me an operation which is attended by less risk, and followed by better results than internal urethrotomy, I will at once say "I am already converted; my heart is with him."

I remain, Sir, your obedient servant,

Portman-square, Oct. 18th, 1880.

W. F. TEEVAN.

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—I am sorry to see in to-day's LANCET that Prof. Clay accuses me of having "made an attack upon him." I had no such intention. If, however, to make a pains-taking, scrupulous, and detailed trial of Chian turpentine in the treatment of uterine and other cancer, and to publish my results, is to attack him, then I am guilty. If to declare my intention still further to prove or disprove its efficacy is attacking him, I am guilty. If to invite Mr. Clay to watch a case with one of my colleagues or myself, and to treat that case as he shall choose, or to allow us to see one of his cases, if this be attacking him, I am guilty. If to utter no single word in criticism of Mr. Clay's theories or facts is to attack him, then, and then only, I am guilty.

Indeed, Sir, Prof. Clay's severest critic has been Prof. Clay himself, whose own words (quoted in my letter of the 9th) tell of pain relieved, hæmorrhage checked, infiltration lessened, and cancers "literally melting away" in a time varying from four days to at most a few weeks. Sure nothing quicker was ever achieved by magic or spell in the Middle Ages—

"Eye of newt, or toe of frog;
Wool of bat, and tongue of dog,"

never worked more mightily. And yet in the same breath

THE MASON SCIENCE COLLEGE has made a good beginning forty-four students having already entered.

Mr. Clay complains that others with whom the drug has proved uniformly worthless have not tried it long enough, or have used the wrong turpentine, or, worse still, as in the instance of Mr. Lawson Tait and myself, he replies only by an unworthy innuendo.

In conclusion, let me say that since I began this letter I was asked to see a patient in consultation with a gentleman (name and address enclosed) who has been under Mr. Clay's care (which case, curiously enough, turns out to be one of those referred to by Mr. Lawson Tait), and is still taking his pills. She informs me that the pain grows worse, and on examination her doctor tells me that the progress of the cancer has not been affected by the Chian turpentine since he examined her when Mr. Clay first saw her. In short, the case is in a condition of active growth.

Sincerely hoping that a cancer cure may be discovered which will be useful in other hands than those of the publisher,

I remain, Sir, yours, &c.,

J. HICKINBOTHAM.

Broad-street, Birmingham, Oct. 16th, 1880.

To the Editor of THE LANCET.

SIR,—Mr. Clay's letter avoids all the points raised in those of Dr. Hickinbotham and myself, and his retiring under the shelter of an insinuation will do little to establish his assertions.

The claim of the cancer-curer has been put forward so often and so vainly that any repetition of it must at once be met with incredulity. Mr. Clay's method of publication is not such as to overcome that, and there is nothing to be heard in Birmingham to diminish it. Mr. Clay's communications appeared in the local daily papers, and since that we have heard of cases of all kinds of cancer flocking to him, and of his retailing to them his mixture and his pills. But not a word has reached us about a cure, save that one case of Dr. Drury's, which so unfortunately died with symptoms, as described to me, uncommonly like those of an ordinary death from cancer. Of this case, still more unfortunately, no post-mortem is recorded.

Surely, if this drug has the effect claimed by Mr. Clay, his colleagues must know something of his astonishing cures. But I cannot learn that they do. The details, scant though they are, which Mr. Clay gives of his cases, are quite sufficient to show that he has not attached sufficient importance to two very common incidents in the history of uterine cancer, and this omission fully explains all that he has written on the subject. Let him submit his cases to his colleagues, or other competent observers, that the actual existence of cancer may be beyond dispute; let him cure a single case, and he will have no reason to complain of the congratulations he will receive from the profession in Birmingham, as elsewhere. On the contrary, let him maintain his present attitude, and no language will be too strong for his condemnation.

I am, Sir, your obedient servant,

Birmingham, Oct. 18th, 1880.

LAWSON TAIT.

To the Editor of THE LANCET.

SIR,—In THE LANCET of July 10th last you kindly inserted a letter from me respecting a case of scirrhus cancer of the uterus, which had apparently derived great benefit from the Chian turpentine as recommended by Professor Clay. Will you allow me to state that since that letter appeared the patient has gradually become worse: secondary symptoms, such as phlebitis and blocking-up of the femoral veins, constipation, alternating with severe and almost uncontrollable diarrhoea, vomiting and inability to retain food on the stomach, &c. &c., soon setting in. And now the cancerous cachexia and emaciation, repeated floodings, and offensive discharge, indicate too plainly that the end is not far distant.

That the turpentine appeared for a time to check the advance of the disease, and also to cause a decided diminution in the size of the tumour, I cannot deny; and as my patient persevered so steadily in taking the pills obtained from the firm of chemists in London whence Professor Clay kindly advised me to obtain them for her, I regret very much having now to give such an unsatisfactory account of her.

Will the gentlemen who wrote to me respecting the further

result of the treatment in this case kindly "accept this intimation."

I remain, Sir, yours obediently,

J. E. KENYON, L.R.C.P. Lond., M.R.C.S. Eng.
Park-road, Bradford, Yorks, Oct. 12th, 1880.

HASTY NOTES BY A RAMBLER.

THE PENNSYLVANIA HOSPITAL AT PHILADELPHIA.

THIS hospital, which now holds two hundred beds, was established about 1751, and with its foundation Dr. Franklin was intimately connected. It gives one the impression externally of an old-fashioned English house, massively, yet commodiously put together. Within are found the most modern and approved arrangements. Perhaps exception might be taken to the resident officers' rooms, one medium-sized room being scarcely sufficient accommodation as the common sitting-room and bedroom of two officers. At the same time, even in this room there is something that will hardly be seen in any hospital in our metropolis—viz., telephonic communication with each member of the staff, and the city central office. While waiting for the doctor, who very kindly acted as showman, it was not a little astonishing to hear verbal inquiries from the police-court concerning the progress of a poor fellow who had that morning been stabbed.

The wards are of good size, not at all overcrowded, with painted walls. The floors are either polished or painted. The absence of fireplaces, and the excellence of the ventilation, are perhaps the most remarkable features in the hospital. It appears that since 1876 they have had in use forced ventilation by fans and flues, arranged both for heated and cold air. In the basement is a revolving fan, eight feet in diameter, and thirty inches wide, driven by steam. This fan, which is calculated to supply 30,000 cubic feet of air per minute, is placed at the orifice of a large fresh air-duct, which leads to the chamber containing the steam-coils for heating (these coils may be in action or not, according to the season of the year) and thence by large smooth flues to all parts of the building. Along the middle of the wards, on either side, are iron supports from floor to ceiling, which communicate at their bases with these smooth air-flues. For about eighteen inches up from the floor the supports are perforated, and through the perforations hot or cold air is continually pouring into the ward. The supports are perforated at the top as well as at the bottom, and through their upper ends they communicate with ventilating flues which carry the foul air away through the roof. I was assured that the wards are always fresh; that there is no difficulty in regulating the temperature; that draught is never complained of; and, what is more important than all, that during the last four years traumatic erysipelas and septicæmia, which were prevalent before, have been almost unknown.

In reply to inquiries concerning the nursing arrangements, I received some exceedingly strong testimony in favour of male attendants in male wards, and was informed that in Philadelphia, except at one or two Catholic institutions, male attendants were invariably employed.

The jerking and jarring of the patient consequent on moving the hospital iron bedstead, whose castors are notoriously faulty, is got over by means of a small carriage with india-rubber wheels of ample size, which is rolled under the bed. By a simple arrangement of screws and levers, the carriage lifts the bedstead off its legs, and permits of its being moved in any direction without discomfort to the patient.

Until the year 1873, accidents, whether drunken or otherwise, were admitted to the wards at all hours of the night—a deplorable arrangement indeed. In consequence of the injustice that was thus done to patients in the hospital, "recent accident wards" were constructed not far from the entrance. These wards contain six male and four female beds. Here all in-patient cases are first placed, and those arriving during the night are kept until next day. And that the accidents proper should not be disturbed by those brought on by drink, there are separate

wards with one bed each, apart from the rest, for the benefit of inebriates.

There is a good pathological museum attached to the hospital, which is carefully looked after by a "microscopist," who is reckoned among the staff of resident officers. In freezing specimens for section-cutting they use rhigolene, one of the first products that come over in the preparation of rock oil. Its specific gravity is '625, and it boils at less than 80° F. They prefer it to ether, on account of its quicker action. For inhalation ether is the anæsthetic most commonly employed. Of late they have used bromide of ethyl, but with what success I failed to gather.

The total absence of clinical clerks and dressers could hardly fail to be remarked, the house-surgeon's assistant taking the form of a four-wheel go-cart fitted with every requisite. Clinical study in the medical curriculum is apparently unnecessary. I was assured that at Jefferson College, which is one of the leading medical schools in this country, a man might take his degree in medicine and go forth to practise his profession *without having ever seen a case!*

IRELAND.

(From our own Correspondent.)

THE contest for the Presidency of the College of Physicians, which was expected with considerable interest, did not take place last Monday, Dr. Hayden having at the last moment withdrawn his candidature, and permitted Dr. Johnstone, ex-Master of the Rotundo Lying-in Hospital, to be elected President unopposed.

The annual conferring of degrees by the Queen's University took place last week at Dublin Castle, the Duke of Leinster, Chancellor of the University, presiding. His Grace referred to the increasing prosperity of the University, and the steady advancement during the academic year just closed; the number of students on the rolls having advanced from 920 to 958. The Prize Essay on the Poetry of Wordsworth, to which was added the Peel Prize, was very favourably reported to the Senate, and was written by Mr. Walter W. Fisher, an undergraduate in medicine of the Queen's Colleges at Belfast and Galway.

At a meeting of subscribers to the Cork Fever Hospital held last week, the report of the Committee of Management, in reference to certain irregularities which were alluded to at the recent inquiry, was adopted. The report found that Dr. Adderley substituted whisky for brandy in the treatment of the boy Crawford from economical motives, but that the medical staff were not aware there was no brandy in the hospital for a considerable time; also that he neglected to carry out the medical directions as to packing, and shaving, and blistering the head of the patient; although the directions about the first procedure might not have been sufficiently definite; and that in administering claret after milk instead of the brandy, as directed, he was to blame. The committee further reported that Dr. Jones's prescription book was removed from the hospital, and they have directed that in future every facility shall be given to the medical officers to take extracts. The physicians for the future are to hold consultations, and the committee have determined that they shall not prescribe any medicine that is not named in the Pharmacopœia, approved of by the medical staff, and sanctioned by the committee. These constitute the principal matters referred to in the report, but as showing that the hospital has done good service I may state that since its foundation in 1822, it has received 113,463 patients, of whom 6185 died, being a mortality of close on 5½ per cent. When these figures are compared with the returns of the Cork-street Fever Hospital in Dublin, it is found that from 1804 up to the 1st of last March, 204,080 patients were under treatment, of which number 15,032 died, representing a death-rate of about 7½ per cent. A meeting will be held on the 4th prox. to elect a successor to Dr. Adderley, when it is probable that the report of the committee suggesting certain alterations in the bye-laws will be formally adopted.

You recently alluded to the inquiry conducted by Dr. MacCabe, in reference to certain irregularities which had arisen in the management of the Kilmainham Small-pox Hospital; and last week the Local Government Board forwarded Dr. MacCabe's report to the Guardians of the South Dublin Union. The charges brought forward by a former

patient of the hospital were considered to be substantiated; but these irregularities mainly occurred during the time Keeley was employed as a pauper wardsman; and the inspector directs the Board's attention to the fact, that the witnesses who had been patients in the hospital bore testimony to the care and kindness with which they had been treated, and to the abundance and excellence of the dietary. The Local Government Board are of opinion that it is never advisable to trust to pauper inmates the administration of stimulants to patients who are so ill as to be unable to claim their rights, or to complain to the superior officers that the stimulants have been withheld; and believe that the remedy lies in the appointment of a responsible paid nurse for night duty. They also make suggestions for the custody of patients' clothing, and recommend that a distinctive dress, or uniform, should be adopted for the inmates.

John I. Donovan, M.D., of Ballincollig, has been appointed to the Commission of the Peace for the County of Cork.

Dublin, 19th October, 1880.

Obituary.

J. PEARSON IRVINE, M.D., F.R.C.P.

DR. PEARSON IRVINE was the son of a medical practitioner at Galgate, Lancaster. After taking the degree of Bachelor of Arts in the University of London, he commenced the study of medicine at the Liverpool Medical School, and after working there for two years he entered at University College, London, in 1863. His quiet and yet genial manner, hard work, and conspicuous ability, soon gained him the regard and esteem of his fellow students. His ability and diligence earned for him distinguished honours at the University of London, where, in 1864, he obtained at the First M.B. examination the exhibition in Anatomy, the medal in Physiology, and honours in Chemistry and Materia Medica, and also at the Second B.Sc. examination the University Scholarship in Geology, and honours in Chemistry and Biology. In the following year his studies were rudely interrupted by the death of his father, and, for family reasons, he had to leave London, and, having qualified, to take his father's practice. He worked in it for several years, and only resumed his duties in London in 1869. He took the M.B. degree in the following year (being awarded the gold medal in Medicine), and the Doctor's degree in 1871.

He intended at one time to settle in Liverpool, where he was well known and esteemed, and he actually practised there for a time. Circumstances, however, led to a change in his plans, and, after marrying, he came to London in 1874, and was soon afterwards appointed assistant physician to Charing-cross Hospital. He lectured there on Auscultation and on Forensic Medicine, and was Demonstrator of Morbid Anatomy.

Dr. Irvine's published writings were not very numerous, for he was one of those who worked much and published comparatively little. All that he wrote, however, was characterised by careful observation and thoughtful comment, and many of the facts which he recorded, although they excited little attention at the time, will probably be often referred to in the future. The subjects on which he chiefly wrote related to diseases of the vascular system and acute specific diseases. At the Pathological Society he was a frequent exhibitor, and some of the most remarkable cases of aneurism brought before the Society of late years were shown by him. The condition of the heart and great vessels in chlorosis long engaged his attention, and the subject was discussed by him in an elaborate paper, read three years ago before the Medical and Chirurgical Society—a paper which contained many important observations, but, to the general surprise, did not find a place in the Society's "Transactions." His most valuable work, however, related to the acute specific diseases. A series of illustrations of the occasional obscurity of the diagnosis of these affections, published three years ago, contains many important practical facts; but his most important contribution to medical literature was the series of articles on Relapse in Typhoid Fever, contributed a year ago to a contemporary. His last work was to expand these into a short treatise on the subject, which is, we believe, just ready for publication, but will be,

alas! posthumous. The practical character of his writings, directed, no doubt, by the knowledge which he gained in earlier life by personal experience of the needs of the practitioner, gives to his work a special value, and would probably have soon secured to him a substantial reward in professional success.

As a teacher Dr. Irvine was most successful. He had a firm grasp of facts, a logical precision of thought, and a clearness and readiness of expression, which are the necessary qualifications for effective teaching. As a colleague, his considerate and kind nature, invariable courteousness; his willingness to oblige, and wisdom of counsel, endeared him to his associates, who now mourn his loss. He was always the same. The writer recalls him as a fellow-student, junior and senior, as a practitioner in Liverpool, and as a friend of later years—frank and sincere, honest hearted, and true to others, willing to serve even at the cost of self-sacrifice, modest and retiring, yet never shrinking at the call of duty. The promise of a successful and brilliant career was just opening before him when his last illness came. Overwork, the altar on which have been sacrificed so many bright young lives in our profession, was the ultimate cause of his death. His devotion to his profession is attested not only by what he published, but by the piles of manuscript that he has left. He thought less of himself than of his work, which he loved "not wisely, but too well."

THE LATE LORD JUSTICE THESIGER.

THE following facts in connexion with the fatal illness of Lord Justice Thesiger, whose death took place on Wednesday last, will be read with interest:—

Lord Justice Thesiger had scarlet fever when two years old, followed by inflammation of the left ear. He was deaf of the affected ear more or less, and suffered from occasional attacks of pain with discharge ever since. Three or four years ago he consulted Mr. Dalby. Finding perforation of the tympanic membrane he advised artificial protection, which gave him the greatest relief and comfort.

Towards the end of his last autumnal holiday, while bathing in a rather rough sea, he was knocked on the left ear by a wave, the organ being at the time, there is reason to believe, unprotected. Fresh mischief soon followed in the affected ear, accompanied by considerable pain in the head. Pyæmic symptoms supervened about a fortnight ago. There was no evidence of meningitis, or cerebral abscess or inflammation extending to the mastoid cells. There was, however, *tenderness along the carotid of the corresponding side*, and considerable stiffness of the neck, which pointed to the inflammation having extended along the internal jugular vein. No collection of matter could be detected anywhere. During the last week he lost all pain in the head. Congestion in base of one lung came on three days before he died, which spread very rapidly. His breathing becoming much embarrassed, he rapidly sank, his mind being perfectly clear almost to the last.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a quarterly meeting of the Council of the Royal College of Surgeons, held on Thursday last, Mr. Savory was re-elected to the Court of Examiners, Mr. J. Hutchinson was elected member of the Court, and Mr. Timothy Holmes examiner in Dental Surgery, in succession to Mr. F. Le Gros Clark.

A communication was received from the General Medical Council to the effect that, after the year 1881, Mechanics would be added to the list of compulsory subjects in the preliminary examination. Sir James Paget gave notice of motion that, after 1881, the College give up to some general educational or examining body the charge of its preliminary examination. Mr. Holden gave notice of motion that the President's annual report to the Fellows of the College be discontinued. Mr. A. E. J. Barker, F.R.C.S. Ireland, was elected *ad eundem* Fellow of the College.

Medical News.

UNIVERSITY OF DURHAM. — At the first examination for the degree of Bachelor in Medicine, which terminated on the 8th inst., the following candidates satisfied the Examiners:—

Ainsley, Thomas George, M.R.C.S.
Barley, David Henry.
Clowes, Herbert Alfred, M.R.C.S.
Dodd, Anthony.
Dowding, A. W. Woodman, L.R.C.P., M.R.C.S.
Eastes, Frederick.
East, Frederick William Allen.
Fenwick, Henry Marshall.
Kempster, William Henry.
Rudd, Walter Edgar.

Seven candidates failed to satisfy the Examiners, and were referred to their studies for six months; and one candidate withdrew.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 14th:—

Catfield, Arthur, Burnt-Ash-lane, Lee.
Graham, Robert, Upper Kennington-lane.
Sisley, Richard, Park-row, Albert-gate.
Steer, William, Courtenay-terrace, Salcombe.
Williams, Augustus Fredk., Ravensthorpe, Northants.

The following gentleman also on the same day passed his Primary Professional Examination:—

Goddard, Walter Horace, St. Mary's Hospital.

COLLEGE OF PHYSICIANS IN IRELAND. — The following have been elected to the Fellowship of this College:—

Hatchell, Joseph Henry.
Sibthorpe, Charles, (Professor of Pathology,
Madras Medical College.)

At a meeting of the Fellows held on St. Luke's Day the following office-bearers were elected for the ensuing year:— President: George Johnston. Vice-president: Walter George Smith. Censors: John Hawtrey Benson, Reuben J. Harvey, Arthur V. Macan, Walter George Smith. Treasurer: Aquilla Smith. Registrar: J. Magee Finny. Examiners in Midwifery: Fleetwood Churchill, J. R. Kirkpatrick. Additional Examiner in Medicine and Chemistry: George F. Duffey. Additional Examiner in Materia Medica: J. Wm. Moore. Additional Examiner in Anatomy: W. G. Smith. Professor of Medical Jurisprudence: Robert Travers.

HARVEIAN SOCIETY OF LONDON. — The Harveian Lectures will be given by Dr. James E. Pollock, on Dec. 2nd, 9th, and 16th, "On the Prognosis and Treatment of Chronic Diseases of the Chest in relation to Modern Pathology."

MR. F. SUTTON, Public Vaccinator, Willingham District, Gainsborough Union, has been awarded the sum of £8 15s. for efficient vaccination in his district. Third time in succession.

THE LATE MR. THOMAS E. SCOBELL. — The friends of this gentleman have placed a handsome brass tablet in Plympton St. Mary Church, and presented an altar frontal in memoriam.

THE LONDON HOSPITAL MEDICAL COLLEGE. — Mr. Frank Hichens has obtained the Entrance Science Scholarship, of the value of £50, and Mr. E. Bryceson that of the value of £30; and Mr. S. Ashley has obtained the Buxton Scholarship of the value of £30, and Mr. H. Guinness that of the value of £20.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL. — Mr. Arthur Shield has obtained both the William Brown Exhibitions of £100 per annum, tenable for two years, and £40 per annum, tenable for three years, and Mr. Bradshaw and Mr. Taylor have obtained the Brackenbury prizes in medicine and surgery, value about £30 each.

UNIVERSITY OF ABERDEEN. — At a meeting of members of the University Council of Aberdeen, held on Monday in the Temple, with reference to the approaching election of Assessor (Professor Hunter in the chair), the following resolutions were unanimously agreed to:— Moved by D. Ferrier, M.A., M.D., F.R.S., Professor of Forensic Medicine, King's College, London, and seconded by the Rev. Peter Forsyth, M.A.,—"That in order to adapt the curriculum of Arts to the wants of the professions room

should be found for such subjects as Chemistry, Botany, History (Modern and Ancient), Political Economy, Modern Languages, and a more extended course of English Composition and Literature; and as it is impossible to enlarge the present curriculum, candidates for degrees in Arts should be allowed to select some of the above-mentioned subjects in lieu of Higher Mathematics, Greek, or other existing compulsory subjects." Moved by Stephen Mackenzie, M.D., F.R.C.P., and seconded by the Rev. John Gibb,—"That as Dr. Bain accepts the principle of option for the Arts degree, this meeting strongly urges the members of Council to vote for Dr. Bain as Assessor."

CAMBRIDGE UNIVERSITY.—At a Congregation held on Oct. 14th the following gentlemen were appointed Examiners:—First M.B. Examination: Dr. Anningson, Caius; Professor Dewar. Second M.B. Examination: Dr. Watney, St. John's; C. Creighton, King's. Third M.B. Examination: Dr. Reginald Thompson, Trinity; Dr. Galabin, Trinity. Medical and Surgical Degrees: Mr. Luther Holden, F.R.C.S., President of the Royal College of Surgeons; Mr. Thomas Bryant, F.R.C.S. Dr. Cheadle, of Gonville and Caius College, was appointed Assessor to the Regius Professor of Physic.

PERTHSHIRE MEDICAL ASSOCIATION.—The annual meeting of this Association was held in the Directors' Room at the Infirmary a few days ago, when the following were elected office-bearers for the year, viz.:—Dr. Robertson (Stanley), President; Dr. Fleming, Vice-President; Dr. Graham, Treasurer; Dr. Baird, Secretary; and Drs. Bramwell, Nairne, M'Naughton, Laing (Bridge of Earn), and Gillespie (Methven), Members of Council. The President made a few introductory remarks; after which, a paper was read by Dr. M'Callum, which elicited considerable discussion. The Society now numbers about fifty members.

SOUTH DURHAM AND CLEVELAND MEDICAL SOCIETY.—The seventh annual meeting of this flourishing society was held at the Stockton Hospital on the 12th inst., when the following were elected officers for the session 1880-81. President: R. W. Foss, M.D., Stockton-on-Tees. Vice-Presidents: G. Middlemiss, Darlington; W. J. Williams, M.D., Middlesbro'. Committee: J. R. Fothergill, M.D., Darlington; J. Farquharson, Stockton; J. R. Pearson, M.D., South Stockton; C. Young, M.D., Yarm; J. Rawlings, Hartlepool; J. W. Eastwood, M.D., Dinsdale-park; J. B. Peacock, Darlington; J. A. Malcolmson, M.D., Middlesbro'; Robert Smith, M.D., Sedgefield. Hon. Secretary: J. R. Morison, M.B., Hartlepool.

THE GERMAN PHARMACOPŒIA.—The Imperial Government of Germany has appointed a commission, which has already commenced its sittings at Berlin, for the revision of the German Pharmacopœia. The commission consists of twenty-seven members, of whom sixteen are professors from various Universities, five are apothecaries, and the remaining six are eminent practising physicians or surgeons. The Prussian War Office has deputed two military doctors and a military apothecary to attend the sittings. Dr. Schmidt, professor of pharmacy at the University of Halle, will act as secretary to the commission, which is presided over by Privy Councillor Dr. Struck, director of the Imperial Sanitary Department.

NORTH-EASTERN HOSPITAL FOR CHILDREN.—On the evening of the 9th instant a conversazione was held at the North-Eastern Hospital for Children, Hackney-road, and more than two hundred guests assembled at the invitation of the President, committee, and medical staff of the institution. The hospital, which was founded thirteen years ago, is placed in one of the poorest and most densely populated districts of the metropolis, precautions being taken that none but fit subjects for treatment shall be admitted to the benefits of the charity. The originator of the institution is stated to have been a lady, a member of the Society of Friends, who took a single room in the district as a dispensary. Subsequently two houses were secured, and in June last new wards were formally opened by her Royal Highness the Duchess of Connaught, and permission was given to name one the "Connaught Ward." The number of beds in the extended hospital is sixty, and in the Convalescent Home at Croydon eight beds were provided. Since the opening 146,000 patients have been relieved, and the average number of out-patients weekly is nearly 1000. The new wards display the most recent improvements for securing

comfort, cleanliness, and ventilation. Communication by telephone is provided all over the building, and there is a complete isolation-ward, which is connected only by telephone with the rest of the building. There has been a most ingenious adaptation of the great flat roof, which has been securely railed in and turned to the purpose of a playground, whence the little sufferers may obtain occasional glimpses of the outlying country. The cost of the construction of the new wards and offices, together with that of the freehold, is about £21,000; and one result of opening the wards is that there is an expenditure in excess of income estimated at £700 a year. There is a debt remaining on the building of about £600, and the expenditure for the past three years has been £400 in excess of income. New subscriptions are therefore much needed.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The usual quarterly court of this Society was held on Wednesday last, Oct. 13th, at 5 P.M., in the Library of the Royal Medico-Chirurgical Society. The President, Sir George Burrows, was in the chair. Applications for relief were read from sixty widows and seventeen orphans; it was resolved that a sum of £1219 10s. be recommended to be granted at the next meeting of the directors. The acting treasurer reporting favourably of the state of the finances of the Society, the court had the satisfaction of voting a Christmas present of £5 to each widow and £2 to each orphan on the list of recipients, and £4 to each orphan on the Copeland Fund. One member was elected. No deaths were reported among the members or recipient of grants, and only one orphan was declared ineligible from age to receive any further assistance.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES.—Mr. T. Veasey, of Baldock, bequeathed £50 to the Hitchin Infirmary and £300 more after the death of his wife. Mr. Henry Ludlam, late of Piccadilly, bequeathed £1000 to the St. George's and St. James's Dispensary. Mr. J. Surman Surman, late of Swindon Hall, Cheltenham, bequeathed £2000 to the Gloucester Infirmary, and £1000 each to the Cheltenham General Hospital and the Dispensary. By the will of the late Mrs. Susan Gorely, of Dover, the following legacies have been left: to the Margate Sea-bathing Infirmary £5000; to the Dover Hospital £1000; to the Hospital for Diseases of the Throat £500; to the Kent County Ophthalmic Hospital £1000; to King's College Hospital £5000; to the Kent and Canterbury Hospital £2000.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning, at the latest.

- ALFORD, H. J., M.D., M.R.C.S.E., has been appointed Public Analyst for the County of Somerset.
- BARTON, T. B., M.D., L.R.C.S.I., L.M., has been appointed House-Surgeon to the West Kent General Hospital, vice Harris, resigned.
- BISS, C. Y., M.B., M.R.C.P.L., has been appointed Honorary Physician to the Western General Dispensary, Marylebone-road.
- BODKIN, P. J. T., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the No. 1 Dispensary District of the Tuam Union.
- BRYDE, J. C., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for the Rural Sanitary District of the Runcorn Union. £120 per annum.
- CURRIE, A. S., M.D., M.R.C.S.E., has been appointed Medical Officer for the Lydney District of the Chepstow Union, vice Tuckwell, resigned.
- DANIELL, G. W., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer for the Blandford Urban Sanitary District. £10 per annum.
- DAY, E. J., M.R.C.S.E., L.S.A.L., has been appointed Public Analyst for the Borough of Bridport.
- DENHAM, J. K., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Demonstrator of Anatomy at the School of Surgery, Royal College of Surgeons, Ireland.
- EVANS, A. L., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Fourth District of the Lymington Union.
- FIELD, A., M.B., C.M., has been appointed Medical Superintendent of the Lunatic Asylum, and Visiting Physician of the Lazaretto, Barbadoes.
- GORDON, J. J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Assistant Medical Officer and Dispenser at the Workhouse and Infirmary, Islington.
- GRAHAM, W., M.D., has been appointed Medical Officer of Health for the Urban Sanitary District of Middleton and Tonge.
- LANGDON, J. W., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Royal Westminster Ophthalmic Hospital, vice Murray, resigned.

LINEKER, Mr. E. H., has been appointed Medical Officer for the Stanfords District of the Castle Ward Union.

MCNEILL, J. P., M.D., has been appointed Public Analyst for the Borough of Tiverton.

MILICAN, K. W., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Kington District of the Stratford-on-Avon Union.

MUTER, Mr. J., has been reappointed Public Analyst for Bermondsey. Remuneration by fees.

NAPIER, Mr. J., has been appointed Public Analyst for the Borough of Southwold. Remuneration by fees.

O'CONNOR, Mr. T. B., has been appointed Medical Officer to the Army and Navy Club, vice Miller, resigned.

PARDINGTON, G. L., L.R.C.P.L., M.R.C.S.E., L.S.A.L., has been appointed House-Physician to the General Lying-in Hospital, York-road, Lambeth, vice H. C. Wright, resigned.

PEARCE, A., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Eleventh District of the Kingsbridge Union.

REID, J., M.D., M.B., C.M., has been appointed Public Vaccinator for No. 3 District of the Fulham Union.

SCOTT, J. W., M.R.C.S.E., L.R.C.P., L.S.A.L., has been appointed Medical Officer for No. 3 District of the Wolverhampton Union.

SMITH, C. C., M.B., M.R.C.S.E., has been appointed Medical Officer of Health for the Redditch Urban Sanitary District, vice Page, whose appointment has expired.

THOMPSON, C. S., M.B., C.M., has been appointed Medical Officer to the Bideford District of the Bideford Union.

THORNLEY, J., L.R.C.P.Ed., L.R.P.S.G., has been appointed Medical Officer for the Sharples District of the Bolton Union.

TURNER, J. E., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Tuam Union Workhouse.

WHITE, R. P., M.B., C.M., has been appointed Assistant House-Surgeon to the Halifax Infirmary, vice Hammond, who has been appointed House-Surgeon.

WHITELEY, G. W., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Rickmansworth South District of the Watford Union.

WILSON, J. S., M.R.C.S.E., L.R.C.P.Ed., F.R.G.S., &c., has been appointed Medical Officer to St. Ann's Dispensary, St. Ann's-road, Stamford-hill.

Births, Marriages, and Deaths.

BIRTHS.

CUTHBERT.—On the 10th inst., the wife of W. W. Cuthbert, M.D., of Debenham, Suffolk, and eldest daughter of S. Grimwade, of Upper Tulse-hill, of a son.

DUKES.—On the 20th inst., at Sunnyside, Rugby, the wife of Clement Dukes, M.D., of a son.

GILL.—On the 15th inst., at Bootham, York, the wife of H. Clifford Gill, Medical Superintendent of the York Lunatic Hospital, of a son.

HUME.—On the 8th inst., at 57, Westgate-road, Newcastle-on-Tyne, the wife of G. H. Hume, M.D., of a son.

HUTCHISON.—On the 10th inst., at Chipping Norton, Oxon., the wife of G. Wright Hutchison, M.D., M.R.C.P.Ed., of a daughter.

MACNALT.—On the 20th inst., at Glenridding Lake, Ullswater, Westmoreland, the wife of Frank C. MacNalty, A.B., M.B. Dub. Univ., of a son (Arthur Salisbury).

STERICKER.—On the 16th inst., at Tollington-park, N., the wife of William Stericker, M.B., of a daughter.

MARRIAGES.

FRASER—TRENCHARD.—On the 14th inst., at St. Augustine's Church, Honor Oak, by the Rev. Dr. Morgan, Donald Alexander Fraser, M.R.C.S.E., L.S.A.L., eldest son of P. Gordon Fraser, Esq., late Colonial Treasurer and Member of the Executive and Legislative Councils of Tasmania, to Elizabeth, eldest daughter of E. P. Trenchard, Esq., of Woodville, Honor Oak.

MILWARD—LOCKHART.—On the 14th inst., at Christ Church, Edinburgh, William Clement Milward, M.B., Surgeon, Army Medical Department, to Elizabeth, eldest daughter of Miles Lockhart, Esq.

O'DWYER—RINGWOOD.—On the 19th inst., at Rochester, by the Rev. G. Eden Peake, Thomas Francis O'Dwyer, M.D., Surgeon-Major, Army Medical Department, to Henrietta Matilda, third daughter of the late Rev. John Ringwood, of Crom, co. Fermanagh.

PITMAN—EVANS.—On the 12th inst., at St. Leonard's Church, Seaford, by the Rev. W. H. M. Buck, William, son of the late Dr. Robert Pitman, of Highgate-hill, to Nellie, second daughter of Edwin Evans, Esq., of Twyn House, Seaford, Sussex. No cards.

STEPHEN—ANDERSON.—On the 14th inst., at St. Mary's, Putney, James Stephen, M.D., of Peterhead, to Agnes, daughter of the late G. G. Anderson, Solicitor, of Peterhead.

STIVEN—THOMSON.—On the 9th inst., at All Hallows', Allerton, Liverpool, Edward W. Fleming Stiven, M.D., of Sunderland, to Annie, daughter of Walter Thomson, Esq.

DEATHS.

BROWNE.—On the 11th inst., at Renaragh, co. Donegal, William Browne, M.D., aged 64.

HOPGOOD.—On the 8th inst., Thomas Hopgood, M.R.C.S.E., L.A.C., of Chipping Norton, Oxon., aged 67.

HOGG.—On the 18th inst., at Connaught-square, Hyde-park, John Hogg, M.D., formerly of Gower-street, London, and of Truro, Cornwall, at the close of his 77th year.

IRVINE.—On the 15th inst., at Mansfield-street, Portland-place, James Pearson Irvine, M.D., aged 38.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INTERNATIONAL MEDICAL CONGRESS, 1881.

STATE MEDICINE SECTION.—Officers Elect: President, John Simon, Esq., C.B., D.C.L., F.R.S. Vice-Presidents: Dr. George Buchanan; Surg.-Major Professor de Chaumont, F.R.S.; Deputy-Surgeon-General Norman Chevers, M.D.; Dr. Douglas MacLagan, F.R.S.E.; J. Netten Radcliffe, Esq. Secretaries: Professor Corfield, M.D.; Dr. Thorne Thorne.

SUBJECTS FOR PAPERS AND DISCUSSION.—On the first day, Measures by which to prevent the Diffusion of different Communicable Diseases from country to country, or within the limits of any single country, will be discussed—e.g., 1. Yellow Fever, Cholera, Plague. 2. Enteric Fever. 3. Syphilis. 4. Glanders, Hydrophobia, Anthrax. On the second day, the Influence of various articles of Food (not including Water) in spreading Parasitic, Zymotic, Tubercular, and other Diseases, will be debated. On the third day the subjects will be: (1) Conditions to be imposed on the legally-qualified Practitioners of one country who may seek authority to practise in another country. (2) Precautions to be taken in Medical Nomenclature and Classification to guard against False Statistical Conclusions.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

LONDON FOGS.

DR. ALFRED CARPENTER's paper, read before the Social Science Congress in Edinburgh, "On the Causes of Fogs in Large Towns," and his subsequent raising of the question of London fogs in particular in a letter published in the columns of *The Times*, come very fitly after Dr. Mitchell had directed attention to the influence of the persistent fog of the autumn and winter of 1879-80 upon the mortality of the metropolis. Dr. Carpenter attributes our metropolitan fogs to unconsumed carbon in the air, and suggests, in view of prevention, the adoption of gas as much as possible for cooking and other purposes in order to reduce smoke, and a tax on fire-grates not constructed to consume their own smoke, together with a rigid enforcement of the law as to smoky chimneys.

A. W. S.—Our correspondent should combine with other practitioners in the neighbourhood to represent to the Registrar the invalidity of the certificates signed by an L.M.

Ambulance.—Dr. Weatherly's Ambulance Lectures are published by Griffith and Farran, St. Paul's-churchyard.

CERTIFICATION OF INSANE PAUPERS.

To the Editor of THE LANCET.

SIR,—A board of guardians contract to pay their medical officers £5 per annum each for certifying to all the so-called pauper lunatics in each district, such arrangement being a rider to the general contracts. It often happens that those certified to as paupers are maintained directly or indirectly by friends after admission to asylum. Does that make them private patients, and therefore improperly admitted and detained? The Lunacy Law, I believe, states the fee to be 10s. 6d. to 21s. per case, and I have a strong impression it is not legal for guardians to contract for this service. Would you or your correspondents kindly inform me on the matter, as some thirty or forty cases per annum are certified to by each surgeon for the above amount, which, in my opinion, is totally inadequate for the services rendered.

I am, Sir, yours &c.,

SUBSCRIBER.

Oct. 13th, 1880.

CURIOSITIES OF ADULTERATION.

IN a recent report presented to the Corporation of Salford by the borough analyst, Mr. J. Carter Bell, several curious illustrations are given of forms of adulteration apparently in ordinary use. The report referred to 154 samples, consisting of 52 milks, 49 breads, 17 teas, 5 coffees, 3 peppers, 4 sugars, 11 wines, 1 baker's mixture, and 5 waters. Of these, 24 were adulterated, consisting of 9 milks, 9 wines, 5 breads, and 1 butter. The five breads contained a chemical compound which is known by the name of baker's mixture. This is now being sold in Salford to bakers for the purpose of mixing with inferior flour. It is made from phosphates of alumina, lime, and magnesia, with sulphuric acid and hydrochloric acid, and Mr. Carter Bell found that it has the effect of spoiling the bread, and making it injurious to health. It also contained a considerable amount of arsenic, the consequence of its being made from impure materials. Mr. Carter Bell also examined nine samples of so-called unfermented wines and two of ordinary tent wines. Of these nine samples, three bearing labels stating that the bottle contained "pure grape juice," "virgin fruit of the vine," &c., consisted of sugar, tartaric acid, salicylic acid, and colouring matter, with a considerable quantity of copper, the result, doubtless, of ignorant or careless manufacture. Grape juice was, in Mr. Carter Bell's opinion, entirely absent. Another sample, labelled "Pure and genuine unfermented fruit of the vine," was evidently a composite article artificially made, and so carelessly prepared as to contain alcohol. One sample of unfermented wine imported from abroad contained some grape juice; but the presence of alcohol and an abundance of yeast cells showed that fermentation had not been arrested. One example was labelled "The selected wine of the Temperance Fraternity." This was an ordinary low class fermented wine, containing a large amount of alcohol. Of the nine samples of the so-called unfermented wines, only one was genuine and was what it professed to be, "Pure grape juice entirely free from alcohol." The samples of tent were sweet and highly alcoholic wines, one sample containing as much as 40 per cent. of proof spirit. This wine had evidently been strongly brandied, no natural wine containing anything like this proportion of alcohol. The number and variety of these so-called unfermented wines testify to a large demand for articles of this class; but the examinations pointed to the necessity of a very careful discretion in their selection. Three samples of water taken from the lodge of a manufactory were so highly contaminated with sewage matter as to make them dangerous to health.

Weak Sight.—There are no advantages, optical or ophthalmic.

MEDICAL ASSISTANTS AND THEIR RELIGIOUS PERSUASION.

To the Editor of THE LANCET.

SIR,—Kindly permit me to make a few remarks under this heading on behalf of medical assistants, with the hope that they will be broadly considered by the respectable and unprejudiced members of the profession.

I am a medical assistant, and lately had occasion to advertise in THE LANCET for a re-engagement. To my advertisement I got several replies from medical men both in town and country practice, the majority of whom desired to know my religion. My answer was, "I am a Roman Catholic," at the same time mentioning I had lived with several Protestant gentlemen, and that my religion never caused the least inconvenience to them, or interfered with me in any way whatever in the discharge of my duties. To my astonishment, I received replies expressing regret that my religion was Roman Catholic. One was couched in the following words:—"The majority of my patients are Protestants, and I fear it (your religion) would be disagreeable for me as well as for them. Only for that I should be glad to accept you as my assistant." The other replies I received were of a similar character.

Now, Sir, surely it is time this bigotry and fanaticism, which still seem to infect the minds of some members of the profession, ought to give place to a more healthy condition. We can well understand how the evil prevails among ministers of religion; but its existence in medical men appears to me to be a mockery and a farce. How few members of this class we find attending church or chapel themselves; certainly their duties do not always prevent them, and yet they make the strictest inquiries about the poor hard-worked assistant's religion, as if it were a part of his duties to administer the word of God "to his household." I consider that the religion of a candidate ought never to debar him so long as his other qualities in every respect were found to be satisfactory. I am certain, however, that the competent and respectable man who may sometimes be placed in this position meets with sympathy from the generous and high-minded, of whom, thank God, our profession can boast a vast majority.

I fear, Sir, I have trespassed too much on your valuable space; but the subject, I hope, will answer as an apology from,

Yours &c.,

October, 1880.

SAUVE QUI PEUT.

Migrator.—A letter addressed "Medicus, Bazaar Agency, 179, North-street, Leeds," will reach the gentleman referred to.
C. F. H.—The hood is, we believe, of crimson silk, lined with white satin, worn over an ordinary master's gown.

MEDICAL LEGISLATION IN COLORADO.

COLORADO would appear, owing to efficient legislation in Central States, to be overrun with quacks and pretenders to medical science. At the last meeting of the Legislature, the State Society accordingly appointed a Committee to present specified matters which require legal adjustment, and a Bill for the regulation of the practice of medicine was the outcome. This measure is the object of unsparing ridicule by the *Rocky Mountain Medical Review*, which characterises the Bill as "a squib, a parody, or, as Orpheus C. would say, a 'sarkasm.'" Our contemporary gives the leading features of the scheme as follows:—Five physicians are to be appointed by the Governor as an examining board; they are to prepare one thousand questions and publish the same. Each and every physician is to present himself for examination, and must answer six questions upon each branch of medical knowledge; these questions being chosen by lottery from among the thousand. There is to be a paraphernalia of tin boxes, locks, keys, envelopes, and seals, and provision is made that no candidate during examination shall be allowed to absent himself for any purpose without being attended by two members of the examining board, and even then for not more than fifteen minutes. Finally, after the board has examined all the candidates, they in turn are to be examined by a committee selected by the late examiners! For this work the gentlemen appointed, presumably practitioners of standing, are to receive the handsome remuneration of three dollars per day, they being employed, it is calculated, about "thirty days in each year."

Surgeon-Major, 7th Bengal Cavalry.—The case is one for local help.

THE CRISIS AT GUY'S HOSPITAL.

To the Editor of THE LANCET.

SIR,—The very humiliating position in which the representatives of the medical staff of Guy's Hospital have placed themselves and their colleagues by withdrawing themselves from their self-asserted position—let that position be tenable or not—is at once a sad loss of dignity to themselves and humbling to the whole profession. Removed from the dignity, either assumed or real, of a factor in the conduct and management of one of the greatest of our national charities, which, in common with all the hospitals of this country, is dependent for the very essence of its utility on the unremunerated services of members of the hospital profession; for without these services where would these charities be?

A sense of satisfaction ran through the profession, that at last one of its chief representative bodies had asserted its claims to a voice in the management of one of the oldest and most renowned of our medical charities; and had the whole staff of Guy's resigned, rather than yield, surely no respectable member of the profession would have accepted office in their place, and the profession would have stood by them and supported their action. As it is, I feel, and others will equally so, I am confident, that the Guy's staff have sacrificed their credit and the fair fame of the profession. Never has such an opportunity occurred for the profession to assert itself in a spirit at once honourable and benevolent, and never has such an opportunity been so injudiciously lost.

Had the staff of Guy's persisted, the profession would have been at one with them, and said of them, with Addison, "It is not in mortals to command success; we have done more, Sempronius—we have deserved it." Whereas now it must feel, in the language of a higher authority "A city divided against itself cannot stand." Such is the position of the staff of Guy's Hospital.

I am, Sir, yours obediently,

October, 1880.

A GENERAL PRACTITIONER.

THE USE OF IMPURE MATERIALS IN ERECTING BUILDINGS.

To the Editor of THE LANCET.

SIR,—I notice in your issue of October 9th some remarks by a correspondent on the necessity of using pure water in preparing mortar for the erection of new buildings. But how much more probable is it that another material of which mortar is largely composed contains a much larger proportion of impurity, and is more likely to produce the bad effects which I, too, have often found to arise in newly-built and plastered buildings. Road-sand, which is so much used in making mortar, is the sifted sweepings of the streets and roads of and near towns, and contains a large quantity of droppings of all sorts; and though this is often stored in large heaps till wanted, and partly exposed to the oxidising influence of the air, yet it is merely the outside of the heap which is thus purified, and the inside retains and afterwards gives out as gas abominations which are so antagonistic to health. Corporations and other bodies have the power of preventing the construction of erections which are not in accordance with the requirements of their bye-laws. How much more serviceable would be the will and the exercise of it in forbidding the use of material which contains such unhealthy germs, and which really does produce not unfrequently such unhealthy results.

Yours faithfully,

J. H. GRAMSHAW, M.D., &c.,

October, 1880.

Medical Officer of Health for Gravesend.

M.D. Edin.—For the French B.A. a candidate must be at least sixteen years old, and upon registering his name for examination he must produce the following papers:—1. His certificate of birth. 2. A formal application to be admitted to examination, written in his own hand, and countersigned by his father or guardian if he be a minor. The same formalities are required for the B.Sc. The programmes of these examinations can be obtained from the publishers, who are Delain, 66, Rue des Ecoles, for the Baccalauréat ès-lettres, and Hachette, 79, Boulevard St. Germain, for the Baccalauréat ès-Sciences. As regards the curriculum of the Faculty of Medicine, "M.D." should consult the forthcoming Students' Number of the *Progrès Médical*, or the *Guide de l'Étudiant*, published by Delahaye; or a book by Dr. Hardwicke, entitled "Medical Education and Practice in all parts of the World" (Churchill, 1880).

Kentigern.—Friday, November 5th.

COLOUR-BLINDNESS AND RAILWAY EMPLOYÉS.

To the Editor of THE LANCET.

SIR,—I cannot but think that Mr. Biggs's letter on the above subject in your last issue is calculated, if it produce any effect at all, to do much harm by inducing a false security.

Your correspondent seems to imagine that because certain railway companies have enjoined that candidates for employment in their service shall be tested as to their colour perception, it may be assumed that this is efficiently done; yet he admits that he himself for some time used a test which he subsequently found to be utterly untrustworthy. It is true that since that discovery he has adopted another method, which is certainly original, but which, as it seems to me, is much more open to fraud and other sources of fallacy than the test which it superseded. The contemplation of such a treasure as a library, containing scores of books bound in all the colours of the rainbow, must have added much to your correspondent's serenity, or he would never have been "satisfied" by the candidate picking out a few books of conspicuous hues. Putting aside altogether the question of fraud on the part of the candidate, to which the test is obviously remarkably open, he stands a fair chance of honestly passing, even if he is colour-blind. He has to pick out four books; the blue and yellow hardly ever cause any difficulty; the red and green remain, and it is just these colours which confuse the colour-blind, but the latter does not confound all shades of red with all shades of green. Given a red and a green of equal intensity, the one or the other will seem to him the darker according as he is red- or green-blind. They will appear to him as shades of one colour, and, if off his guard, he may call them both by one name; but he knows by experience that the one shade is what other people call red and the other green. He probably looks upon the distinction as an unnecessary refinement, but considers it prudent to humour the crochets of the examiner, and names the colours accordingly correctly; yet such a man would be totally unfit to act as a signalman or driver, as he could only distinguish red from green when the two colours were seen together, and would even then confound some shades of the one colour with some of the other.

The essentials of a good test are that it shall be quite independent of the names of colours; that it shall be simple and rapid, applicable to large numbers at a time, and secure against fraud. The only test which has hitherto been found to fulfil all these conditions is Holgrem's. This test depends on the comparison of different colours, Berlin wools being the material employed. It is not the more pronounced colours which are most useful in detecting colour-blindness (though these serve to determine its nature), but the pale greens, drabs, and greys which the colour-blind always confound.

Your correspondent implies his belief that the prevalence of colour-blindness in this country has been exaggerated. Our data are not yet sufficient to enable us to determine whether this is so or not; but out of the 920 medical men present at the meeting of the British Medical Association at Cambridge in August last, 745 were tested as to their colour-perception. Of these, 19 were found to be defective in this respect; so that even if we suppose, which is, of course, most improbable, that all those who were not tested had normal colour-perception, we have amongst an educated body of men more than two per cent. whose sense of colour is defective.

That more facts are needed everyone will admit, and it is to those who hold appointments like your correspondent's that we must look for such facts. If those who hold such posts would test all employes using the same tests and record their results, much valuable information would be obtained.

A medical man in Wales is carrying out Holgrem's test on a large scale, and I shall be happy to give anyone having similar opportunities the details of the tests which he is employing, which are identical with those used at Cambridge. It will be a relief to such to learn that the possession of a chromatic library is not a *sine qua non*.

I remain, Sir, yours truly,

W. ADAMS FROST, F.R.C.S.

Wimpole-street, Oct. 18th, 1880.

A Tutor.—We cannot afford space for the publication of the long list of names of those who passed the Arts examination for the Fellowship and Membership of the Royal College of Surgeons at Burlington House in September last. We are informed that 108 passed for the Fellowship, and 258 for the Membership, making a total of 366. The rejections were for the Fellowship 8, and the Membership 114. The examinations take place half-yearly.

TREATMENT OF CHOLERAIC DIARRHŒA BY THE HYPODERMIC INJECTION OF MORPHIA.

To the Editor of THE LANCET.

SIR,—Mr. Hardman will, doubtless, be glad to hear that the treatment of the above disorder which he so strongly advocates (*THE LANCET*, Oct. 2nd) has in my hands proved equally successful and gratifying.

A case of very severe diarrhœa which occurred in my practice some three years ago, in which I used the injection, impressed me very much by reason of the rapid change from a condition of great gravity to one of comparative ease and safety. Everything swallowed was immediately rejected; the dejections escaped without control into the bed; the eyes were deeply sunken and dull; the voice little more than a whisper; and cramps and capillary congestion of the surface general. I think it was the utter impossibility of anything being retained by the stomach in this case which suggested the subcutaneous method to me. I injected one-third of a grain of morphia, and within half an hour all the symptoms, but especially the cramps and purging, were relieved.

I have used this method of treatment in indicated cases ever since, and not unfrequently have heard the patient say he was "never purged after the injection."

I may add that lately in a case of subacute gastritis from alcoholic excess, the vomiting was quickly checked by the injection of one-sixth of a grain of the alkaloid, the usual remedies being of no avail. The same good effect was noticed in three separate attacks.

I am, Sir, yours faithfully,

Darlington, October, 1880.

L. EASTWOOD.

To the Editor of THE LANCET.

SIR,—I reside in a manufacturing district, and am in the habit of recommending several of my patients in the summer to go to Blackpool, believing it to be a health-resort, where pure air can be breathed, and wasted energies revived. I am, therefore, very much astonished to read in your journal of Oct. 2nd the article on Diarrhœa by Mr. Hardman, of that town. He gives the history of only thirteen severe cases, as he says, taken at random from a considerable number of which he has the notes; and as, according to the dates given, almost all these cases occurred in one week, I should certainly like to know what is the cause of so much diarrhœa in Blackpool. There are nine medical men there, and if each one gets his average of such cases, there must have been in August last some hundreds of cases of this complaint in the town; and in the interests of myself and other medical men, who advise their patients to go to Blackpool, I must ask Mr. Hardman to explain how it is that such a serious *insanitary* condition is allowed to prevail! for until this is removed I shall certainly refrain from sending patients to Blackpool for their health.

Summer diarrhœa generally affects young children; but all these cases are in adults, which renders the matter much more serious.

Yours &c.,

M.D.

Oct. 6th, 1880.

INFANTILE DIARRHŒA AT WIDNES.

To the Editor of THE LANCET.

SIR,—In *THE LANCET* of the 2nd inst. you quote some remarks said to have been made by the chairman of the Widnes Local Board, and you very properly add that "this statement convicted the Local Board of the grossest negligence with reference to the removal and deposit of refuse."

As I am responsible for the statement which was made, will you permit me to say, for our credit's sake, that I also expressly stated that as soon as our inspector observed that the condemned fruit was taken by the children he at once took measures to have all such material destroyed, or placed out of reach; and this very obvious precaution has been, to the best of my knowledge, uniformly observed.

Yours truly,

EUSTACE CAREY,

Chairman of Health Committee of the

October, 1880.

Widnes Local Board.

USE OF ALCOHOL IN PNEUMONIA.

SURGEON JOHN HOYSTEAD, Station Hospital, Hyderabad, writes as follows on this subject:—

"When quartered at Fort Dakka (four stations up the Kyber line route to Cabul) it was my privilege to treat successfully numerous cases of pneumonia occurring in the 35th Punjab Native Infantry, all of a low type, with liquid rusty sputa and rapid hepatisation. Before my arrival at Dakka, one and occasionally two men were dying daily from that disease. The morning of my arrival at the Fort one man died of pneumonia, and I took charge of eight desperate cases. I remained at Dakka two months, and lost but one case, a very old soldier, with worn-out constitution and double pneumonia. The secret of success in the treatment of these cases was the immediate exhibition of alcohol, rum or brandy, in large quantity, from six to eight ounces in twenty-four hours, the ordinary stimulating plan of treatment with carbonate of ammonia, &c. &c., and constant counter-irritation to chest-walls, no doubt also assisted nature. Generally quinine, in ten-grain doses night and morning, was employed to hit the malarial complication. My object in placing such patients upon a liquor ration from the first was, if possible, to prevent the disease running into its secondary and tertiary characteristics, which it usually did with terrible rapidity when unassisted by art."

Dr. Williams—The Calendar of the College of Surgeons contains the names of 1215 Fellows, 558 of whom obtained the distinction by after examination. The Members of the College number nearly 16,000.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir J. SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year.....	£1 12 6	Six Months	£0 16 8
To CHINA AND INDIA	One Year, 1 16 10		
To THE COLONIES AND UNITED STATES..	Ditto, 1 14 8		

Post Office Orders should be addressed to JOHN CROFT, THE LANCET OFFICE, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

Medical Diary for the ensuing Week.

Monday, Oct. 25.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL. — Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL. — Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL. — Operations, 2 P.M.

ST. MARK'S HOSPITAL. — Operations, 2 P.M.; on Tuesday, 9 A.M.

MEDICAL SOCIETY OF LONDON. — 8½ P.M. Mr. William Adams, "On Cases of Paralysis, with Contraction of one Leg following Pelvic Abscess in Women, and of both Legs following excessive loss of Blood after Miscarriage."

Tuesday, Oct. 26.

GUY'S HOSPITAL. — Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL. — Operations, 2 P.M.

WEST LONDON HOSPITAL. — Operations, 3 P.M.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY. — 8½ P.M. Mr. Henry Morris, "On a Case of Aneurism of the External Carotid, in which, after failure of the Ligature of the Common Carotid, the old Operation was successful." — Mr. Savory, "On a Case of Abscess in the Neck, which in its course destroyed a large portion of the Carotid Artery, Jugular Vein, and Pneumogastric Nerve."

Wednesday, Oct. 27.

NATIONAL ORTHOPÆDIC HOSPITAL. — Operations, 10 A.M.

MIDDLESEX HOSPITAL. — Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL. — Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL. — Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL. — Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.

HUNTERIAN SOCIETY. — 8 P.M. Dr. Herman: "Notes on some Cases of Dysmenorrhœa." — Mr. Waren Tay will exhibit some Patients.

Thursday, Oct. 28.

ST. GEORGE'S HOSPITAL. — Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — 1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL. — Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE. — Operations, 2 P.M.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM. — 8½ P.M. Consideration of Laws and Election of New Members. Mr. Hutchinson, "On a Case of Intracocular Hemorrhage"; Dr. Hughlings Jackson, "On the Eye Symptoms in Locomotor Ataxy"; Mr. Higgins, "On Hypocleral Cyclotomy." — 8 P.M. Living Specimens: Dr. Gowers, "Optic Neuritis from Intracranial Disease (two Cases)"; Mr. Nettleship, "Double Iritis with a Growth on one Iris"; Mr. J. E. Adams, "Peculiar Opacities in the Vitreous after Injury."

Friday, Oct. 29.

ST. GEORGE'S HOSPITAL. — Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL. — Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M.

Saturday, Oct. 30.

ROYAL FREE HOSPITAL. — Operations, 2 P.M.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.	

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed. Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom. The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers. A First Issue is made each week at seven o'clock on Friday morning, for the Wholesale Houses only. A large Colonial Edition is also published for despatch the same day.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

An Address ON THE TREATMENT OF PUERPERAL FEVER.

*Delivered before the Midland Medical Society at Birmingham,
Oct. 20th, 1880,*

By J. MATTHEWS DUNCAN, M.D.

ALTHOUGH only a few years ago it was far otherwise, the remark may now pass unchallenged, that there is no such disease as "puerperal fever," whose treatment is yet my subject for this evening. That name has been for a century in constant use, and indicates, though with deplorable lack of precision, a group of diseases for whose designation it may meantime be, for convenience sake, retained. Whatever designation we may adopt, we experience no difficulty in recognising the diseases meant, and there is no hesitation in ascribing to them the highest place in importance to lying-in women who suffer and die, as well as to medical men who observe and treat. Their baneful influences, including their mortality, exceed those of any other group of diseases of childbed. It is truly said that childbearing proves fatal to every hundredth mother, and it may be added that, of this fatality, the far greater part is due to these diseases. How enthusiastic does the study of them become when we contemplate the reduplicated danger of mothers who have just borne a first child; how grave and awful when we regard the rapidly-increasing perils of mothers who count their children by numbers that rise higher and higher into the physiologically excessive.

It is misleading to estimate the importance of puerperal fever by death alone. The habit of doing so is easily accounted for. Mortality is a result, plain and infallibly ascertained and numbered. The modern science of statistics, and the connected statistical arguments deal almost exclusively with death. In most writings it is implied that escape from early death is recovery—an error which it is only necessary to mention in order to ensure its recognition. Death is a simple result, final, unconditioned pathologically—an end, to which various pathological routes may guide. So-called recovery is not its antithesis in practice, whatever it may be in theory. In many cases so-called recovery is anything rather than restoration to health; it is merely an escape, more or less narrow, from early death. The escape is generally into paths which lead to health ultimately; often it is into paths which lead to death more or less directly, more or less slowly, and after a lapse of months or even years. Recovery as antithetic to death is a very indefinite matter. Puerperal fever ends in death or in survival of the immediate attack. Such survival may be in good health or in wrecked health, or it may be in grave and progressive disease.

A good deal of undesirable mystery and much of positive error has been propagated in this subject by the long-continued and still persistent practice—a mere practice, now, without any rational basis—of regarding puerperal fever as occurring chiefly in epidemics. In its prevalence it has a seasonal variation, which Buchan and Mitchell have traced, and which closely resembles that of erysipelas; but it has no periods of epidemic raging; or, rather, none have been demonstrated. Individual epidemics of cholera, small-pox, scarlet fever, measles, and other diseases, have been well described; cycles of epidemics of these diseases have been pretty well traced, but no such demonstration or tracing has been made in the case of puerperal fever. Histories of many so-called epidemics have been written, but their descriptions fail to prove the reality of their epidemic character. Were this disease prevalent in epidemics so frequent as authors ask us to believe, we should be able to give from statistical data a complete account of them in their individual and in their grouped or cyclical characters, but statistics afford no evidence of the occurrence of any epidemic. The group of diseases called puerperal fever is ever with us, its frequency varying slightly, never rising very high, never sinking very low, always governed by an average. This

average of deaths in every community is an average of awful calamity, which we struggle to diminish by treatment, glad to escape from the task of encountering the additional evil that would be raised by epidemic prevalence.

In a meeting of practitioners such as this I make these preliminary remarks as a mere exordium, well knowing that nothing is required to heighten your sense of the interest and importance of the subject. Medical studies do not blunt the sensibility or harden the heart. Who is there so callous as not to be moved by the enthusiasm of a physician when he stands at the bedside of a young wife suffering, and, perhaps, dying, in giving life and joy to others? All of us are frequently in this responsible position, and I dare to say that none of us feels quite satisfied in it. There is not the vacant, hopeless, observation of acute hydrocephalus, nor the melancholy soothing of cancer, but the restless care of a fever, the watching narrowly with a view to judicious interference, watching, well done in proportion to the depth of knowledge and the quickness of intelligence and the warmth of sympathy; interference, judicious in proportion to the wisdom and experience and skill of the watcher. The wisest feels most deeply the want of more knowledge. The most experienced feels most acutely how little power he has to govern a case, how often he is a mere looker-on.

Our topic for this evening is the treatment of puerperal fever—how to interfere judiciously, how to govern a case, how to conduct mere management. My remarks are thrown into the form of an address, suited, I hope, in some degree, for this occasion. I do not propose to elucidate any special point, to drive home a scientific argument, to suggest a novel treatment. Such are the objects of the communications which will be laid before you during the session. Mine is to give an address according to the invitation with which you have honoured me, not to read a paper. An address has its own useful place in our meetings; but it is never to be forgotten that the work of our societies is not the hearing of addresses, but the attentive listening to, and careful scrutiny of, papers, generally short, and occupying narrow limits, embodying the results of original observation and reflection. An address may be, as this is, an attempt to review the past, and to sketch the present, condition of a great matter.

In puerperal fever, as in most diseases, practice is more based upon theory than upon our often too much vaunted experience. We condemn old practices chiefly because we have new theories. There can be no doubt that this is a just proceeding, if our new theories are not mere fancies but based on increase of knowledge; and accordingly I shall show the connexion of our new treatments with our new theories. However flimsy these theories may be, they are our guides, and they delight and encourage the inquiring spirit of the human mind. Cullen and Heberden based their therapeutics on Hippocratic observation. The Hunters and Laennec on morbid anatomy. The moderns specially on histology and chemistry. Bacteria and sepsin rule us to-day, while mere inflammation has lost its supremacy. We do not see in our change of treatment evidence of any change in the disease, but the reflection of our increase of knowledge.

A great old obsolete plan of treatment is not to be regarded as erroneous or bad, and so contrasted with ours. Such plans were not the fruits of caprice, nor the *ipse dixit* of great and famous physicians, but represented the knowledge and wisdom of their times. I have lived long enough to see the gradual decadence of the antiphlogistic treatment of Gordon, with its venesection and leeching and blistering. Heat of skin, rapidity of pulse, and abdominal pain were the notes of inflammatory disease which was to be attacked and cured if possible. Since these days much confusion of doctrine has prevailed, and there have been many variations of treatment. The view that the disease was a special fever occurring in many forms, such as are described by Ferguson, led to correspondingly various treatments, which were not materially affected by the great phlebotic discovery which in this country we associate with the name of Robert Lee. Indeed, since the days of antiphlogistics, no great therapeutical plan has been common, for no great medical doctrine has prevailed. The profession has relied much on special drugs in the hope of curing rather than treating the disease whatever it might be; and latterly many have devoted themselves to treating symptoms. Some years ago we heard much of medicines to make the pulse slower; now, in accord with our temperature diligence, we have great stress laid on reducing it.

Living among great physicians, and, as a young practitioner, willingly submitting myself to them, I have seen several changes of treatment. In my earliest days, as a hospital resident and for some time subsequently, while bleeding was a decaying treatment, the great remedy was calomel and opium, and I well remember the improvement in the prognosis which was based on the fortunate but rare occurrence of pytalism. Gradually the calomel disappeared, because it almost always produced painful and debilitating diarrhoea, and it was replaced by blue-pill. Then the mercurial disappeared entirely; and, under the influence of the teaching of Graves, opium alone became the great resort; and this medicine still keeps its place as a valuable adjuvant in treatment. While its great utility is incontestable, I feel bound to record that I have often seen it act injuriously from its being used in far too large doses. The last treatment which had a passing pre-eminence was the copious administration of food and alcohol. I have been in practice during the whole existence of this modern and still-surviving plan—not a mere spectator or willing subject of older advisers, but taking an active part in the management of grave cases. Experience has taught me that there is no more delicate work in practice than the arrangement of the food and drink; and no part of treatment have I seen so overdone, with the result of producing intense present discomfort, as well as an injurious influence on the progress of the cases. This mismanagement has always been the excessive administration of alcoholic stimulants, apparently under the belief that if a little is good more is better, and that excess is scarcely attainable and not to be feared. The practice was derived from London, and I hope London will have the honour of putting an end to it. Stories of quantities administered, that are scarcely credible, are probably still in all your memories; and I can testify from my own knowledge that they are not exaggerated. Great practitioners boastfully narrated how much they had succeeded in pouring into their patients, and this when they were not in a short critical period of weakness; and the brandy practice and boasting extended even to the treatment of babes!

Although I have seen no treatment by ipecacuanha, yet there have been in my time several "cures" introduced, which have fortunately passed quickly into oblivion. The search for "cures" is, as yet at least, a wild-goose chase. We have a long course to pursue in acquiring intelligence regarding the disease to be cured before we can hope even for a well-established plan of treatment.

It is not uncommon, nowadays, to confine the name of puerperal fever to septicæmia and pyæmia occurring after delivery. It appears to me, however, to be better, even on mere theoretical grounds, to include all the ordinary diseases of the lying-in chamber, which are accompanied by fever, and which may be fatal. In practice we cannot meantime maintain the limitation to septicæmia and pyæmia, because in many cases we cannot be sure of our diagnosis, and because a case may begin as one disease and be complicated with another as it advances.

In addition to septicæmia and pyæmia, which are the result of the growth in the blood of certain micrococci having the power of rapidly multiplying, we have sapræmia, or mere poisoning by the chemical products of putrefaction, and we have simple or traumatic inflammatory fever.

Simple inflammatory or traumatic fever is often very alarming on account of the severity of the symptoms, also on account of the extent of the inflammation. There seems to be in addition to the influence of traumatism, in some cases, a temporary inflammatory diathesis, the region of the womb being not the only one attacked, but, in addition, the kidneys or the organs in the chest, or the encephalon, or all at once. Sometimes the inflammation attacks the remote parts, while the womb and its neighbourhood are unaffected by it. But most frequently the disease is a parametritis, or a perimetritis which may become so extensive as to form a general peritonitis.

In these cases, when pain is great, the pulse quick and hard, the skin hot and dry, there is generally much benefit derived from the old antiphlogistic regimen and treatment; but now the regimen and treatment are not used with what we may call the rigour and severity of our predecessors. Patients are generally allowed soup daily, in addition to the appropriate quantity of slops, that is, bread and milk and tea. Venesection is rarely practised. I have neither used the lancet, nor do I remember hearing of its use for the last twenty years. Leeching is frequently resorted to, the site being above the groins on one or on both

sides, that side of course being preferred in which there happens to be most pain. Not fewer than a dozen leeches are applied, and the bleeding may be encouraged to a loss, always only vaguely estimated, and varying according to the hardness of the pulse and the constitutional condition of the patient. The leeching may be repeated if necessary. It is generally followed by well-marked relief of pain and some improvement of the general condition.

While bleeding is most relied upon in the earliest days of the fever, blistering has occasionally a place in the later days. Poulting is always used. The very painful turpentine stupe is a common application; but in some cases the blister is of great value. It gives much less pain than the turpentine stupe, often, indeed, very little pain, and its effects are not so transitory; besides, it causes a copious transudation of serum and subsequently of pus. The blister should be large, even to covering the greater part of the abdomen between the umbilicus and pubes. It should be an old-fashioned rising blister, the *emplastrum lyttæ*; not such blistering as is nowadays much, and perhaps usefully, employed in other cases, where a blistering fluid raises very rapidly the epithelium, producing little irritation, the skin being only slightly and temporarily reddened. Great irritation and effusion of serum copiously are what is desired here.

Opium is almost always used, and there are great variations in the quantity given, and in the preparation that may be preferred. A good dose of one or two grains at bedtime, to procure sleep, is an almost constant prescription. Advantage is often also found in using the drug during the day if it does not stop the secretions, dry the mouth, and destroy the inclination to take and the power to digest food. In cases where there is much pain, and especially a state of nervous agitation of body and restlessness of mind, the repeated daily use of the drug is most valuable. Many rely upon the copious administration of opium, without any regard to the peculiarities of the case, considering the continued moderate narcotism it produces as the most favourable condition for the patient's recovery. I do not adopt this view of the utility of opium and its preparations, and therefore do not press its use as an object in itself, but use it freely when it does not disagree, as a stimulant narcotic to allay restlessness, to soothe pain, to procure sleep.

In severe cases, with much local peritonitic tenderness, a mercurial is advantageously combined with the opium. Many have a special confidence in the calomel, but I hold that it is generally best given as the simple blue pill, about six grains in the course of the day. Or the blue ointment may be applied on the abdomen or elsewhere. Should evidence of hydrargyrimus appear, the further action of the drug is checked by partial or complete discontinuance of it. Many eminent practitioners, especially in Scotland, make no use of mercurials in any form of puerperal fever.

Ever since I began practice there has been less, and still less, of what is, or used to be, called heroic practice in inflammatory cases; and now it is not uncommon to see them indiscriminately treated by opium and stimulants, with poulticing locally. My own judgment of this important practical matter is that a large number do well on this plan if it is conducted not heroically but gently; that, indeed, in many delicate women, with attacks of slight severity, it is the best plan of treatment. But the antiphlogistic regimen and treatment, as I have sketched it, is proper for the majority of cases, demanding of course such modifications as may adapt it to the peculiarities of each individual example.

The next class of cases, that of sapræmia, or of simple putrid intoxication—poisoning not by an organism multiplying in the blood, but by the passing into it of the chemical products of putrid decomposition—is one upon which much light has been recently thrown, and with the most beneficent results in practice. Like the other forms of the so-called puerperal fever, this I shall treat as a separate entity, and it frequently is so. But it may be combined with the traumatic fever of inflammation, and it is especially liable to be combined with septicæmia and pyæmia. Indeed it has long been, and still is, the habit to speak of septicæmia and pyæmia as diseases of putrefaction, but this is a mistake. Putridity of the discharges is not an essential part of these diseases at all, though it often accompanies them. The organisms which cause septicæmia and pyæmia probably take no part in putrefaction. They live in the discharges, and are conveyed or pass into the blood, where they multiply indefinitely. The organisms which cause

putrefaction, whether the bacterium termo, or others in addition, may pass into the blood with the putrid fluids to produce sapræmia, but they do not survive, far less grow therein.

We have, then, in sapræmia, when uncomplicated, a very simple problem. Putrid ichor is absorbed or flows through the uterine sinuses, or otherwise, into the circulation. Its poisonous constituents are eliminated rapidly from the blood; for if the supply is stopped the sapræmic phenomena quickly disappear. When once in the blood it does not increase in it, ferment-like, independently of any further supply. Sapræmia is kept up by a continuous supply of the poison. It disappears when the supply from without is stopped. To stop the supply is the problem of cure.

Fætor of the discharges has to be searched for in all cases of puerperal fever. It may be easily discovered by its strength; or it may be concealed, especially if the patient is kept very clean, and if vaginal deodorising washes are used. The finger, if there is suspicion, or even the whole hand, carefully carbolised, may be passed into the uterus, to find the fætor and its cause, and peradventure to remove them. There may be putridity of discharges alone, but generally there is some decomposing substance, and more than mere bloodclot, a patch of membrane, and probably of chorion, a small bit of placenta, or some hypertrophied decidua mass. Sometimes the putrid fluid is retained *in utero*, and it may be discharged in great gushes, flowing at successive intervals.

(To be concluded.)

CASES OF ANEURISM ILLUSTRATING DIFFICULTY IN DIAGNOSIS, AND THE USE OF ESMARCH'S BANDAGE.

BY WALTER RIVINGTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL.

(Concluded from page 610.)

THE more we see of aneurism the more we see how liable the very best surgeons—may I add the very best physicians?—are to make mistakes in diagnosis. Perhaps it is as well occasionally that it should be so, for the greatest misfortune that can happen to any practitioner is that he should deem himself immaculate. An aneurism may be mistaken in several ways. The surgeon may be fully alive to the possibility of the tumour before him being an aneurism, but may consider that the evidence points to another affection more strongly, as, for example, to malignant tumour. The conviction may or may not be strong enough to lead to action on that basis. In its minor subdivision this mistake was exemplified in the case of the aneurism of the anterior tibial artery. The reverse error of mistaking a malignant tumour for an aneurism is not uncommon. The surgeon may tie, or be about to tie, a large artery on this supposition. One instance of this kind has come under my observation. The artery was not tied because consultation suggested the right diagnosis. In my paper on Intra-orbital Aneurism, in Vol. 58 of the Medico-Chirurgical Transactions, I have adduced some instances in which the common carotid artery has been tied for malignant disease in the orbit, mistaken for aneurism. A paragraph from the paper having appropriate relation to the topic of my present communication may here be quoted:—

“Encephaloid cancer, when very vascular, may be, and has been, mistaken for an aneurismal tumour, for it may possess both pulsation and bruit. Its onset is often obscure, and the case will be still more obscure if the orbital tumour exists alone, and if its development has followed an injury. Loss of vision, exophthalmos, pulsation, noise in the head, and bruit, ceasing when the carotid artery of the corresponding side is compressed, are symptoms of cancer and symptoms of aneurism. Moreover, the encephaloid tumour, projecting outwardly, may yield a soft, semi-fluctuating sensation, peculiarly liable to deceive even the experienced practitioner. In M. Lenoir's case the carotid artery was tied under the impression that the tumour was aneurismal.

The disease had followed a fall on the back of the head, and the only symptoms of differential value were the light whispering character of the bruit, the irreducibility of the tumour, and its extension towards the temporal fossa. Pulsation may be present without bruit, and the diagnosis will then be more obvious. In Mr. Nunneley's case of cancer of the orbit the carotid artery was tied, and this checked the progress of the disease, various opinions having been expressed in regard to the nature of the case. Its exact character was only ascertained at a late period of the disease. Here the diagnosis of cancer was rendered probable by the existence of multiple tumours, and by the continuation of the orbital tumour into the zygomatic fossa. The existence of a tumour in the left temple, in Szokalski's case, continuous with the orbital tumour, and the subsequent appearance of a tumour on the left iliac crest, as well as the slight effects of ligature, are suggestive of cancer.”

A very puzzling case of aneurism in which the nature of the tumour was for some time doubtful came under my care not long ago at the hospital. The varying conditions of the tumour gave rise to two distinct schools of thought amongst the observers of the case, and I learned from Mr. Treves, then the surgical registrar, that the students were divided into two hostile camps, one camp championing the view of abscess, and the other the view of aneurism. My own mind was kept for a week in a state of oscillation. The case was one of aneurism at the bend of the elbow, and is so instructive that some account of it may be acceptable.

Herman C—, aged sixty, a feeble, worn-out man, who had been at one time a large speculator on the Stock Exchange, was admitted into the London Hospital early in February under the care of Dr. Hughlings Jackson. He was suffering from heart disease, and a loud systolic murmur could be heard with the stethoscope. Three weeks before admission he had noticed a lump at the bend of the left elbow, and had experienced a feeling of soreness in all his fingers, and in his thumb, which became blue from congestion. At this time the tumour was of the size of a hen's egg. It was situated underneath the deep fascia, and just at the bifurcation of the brachial artery, which lay in front of it. One-third of the tumour was on the inner side of the bifurcating brachial, and two-thirds on the outer side. An impulse appeared to be communicated to it from the brachial artery, which could be traced over it to its bifurcation. On grasping the tumour between the fingers, the inner side expanded, not the outer. The pulse was feeble at the wrist. Pressure on the inner side of the tumour checked the radial pulse; pressure on the outer side had no effect. The notes taken by Mr. Treves state that, “on compressing the brachial artery, and letting it go, pulsation at once returned to its original condition. There was no gradual filling by several successive beats, but at one bound the tumour became of the same size, and as vigorous as ever. Stopping the brachial did not appear to diminish the size of the tumour in the least. The bruit was soft, and an exactly similar one could be produced over the carotid by pressure with the stethoscope. The measurement round the limb over the aneurism was 10½ in. on Feb. 8th. By the 15th the tumour had increased in size; the linear thrill over it was not so distinct, and the bruit was confined to the line of thrill.” Mr. Treves's notes add, “There is apparently now no lateral pulsation. Pulsation is much more marked on the inner than on the outer side. Abscess theory now pretty generally held.”

This account represents the condition of the tumour when the patient was first seen by myself at the request of Dr. Hughlings Jackson. On careful examination I could not satisfy myself of the existence of lateral or expansile pulsation, either in the extended or flexed condition of the elbow-joint, nor could I hear a bruit. The brachial could be readily traced to its bifurcation over the elastic swelling. I was unable to offer any decided opinion as to the nature of the case. A few days later the patient was transferred to my care, and was kept for more than a week quiet in bed, with ice applied to the tumour. On one occasion I thought I detected a heaving movement in the tumour, and heard a slight bruit, but both were so gentle that it was impossible to form any definite diagnosis. The glands in the axilla were not enlarged. The tumour might have been anything almost—aneurism, malignant tumour, or innocent tumour, or abscess. In favour of aneurism were the earlier history of the case, the situation of the tumour, and the coexistence of cardiac and (as I thought probable) aortic disease. At this time the tumour was increasing in size, for on the 25th it

measured twelve inches and a half in circumference, and had begun to press upon the median and ulnar nerves. There was a peculiar numb feeling in all the fingers, and in the thumb of the left hand. The patient could not close his hand well; on being asked to clench his fist, he did so in a very laboured and imperfect manner. The contour of the swelling was less regular, and seemed to have become flattened, the surface being more extensive and the margins more abruptly defined. On the 27th the diagnosis was still further complicated by the occurrence of rigors, lasting for three hours—from 10 P.M. on the 26th to 3 A.M. on the 27th. The temperature rose and the tumour increased in size. No satisfactory explanation of these symptoms could be offered, but it was stated that the patient had had ague years ago, and had been constipated for the last day or two. My impression is that patients who are the subject of heart disease and disease of the aorta are more prone to rigors than healthy persons, and I believe also that rigors occur occasionally in patients with fatty heart who are approaching their dissolution. At least I have met with one or two cases of rigors which could not be explained on any other basis.

On the 4th of March a careful examination under ether proved that the tumour possessed obvious pulsation. During extension of the elbow-joint, when the fascia covering the tumour was stretched, no pulsation could be felt; but when the elbow-joint was flexed a heaving movement on the inner side became obvious. The existence of bruit was doubtful. There was no pulse at the wrist. The following day both pulsation and bruit were very distinct. I found the pulsation evident over the whole tumour and of an expansile character, and a moderately loud and rough bruit. This fresh aspect of the case at once determined the diagnosis of aneurism, and I gave instructions for the application of digital compression to the brachial artery without delay. Digital compression was carried out under the superintendence of my house-surgeon, Mr. J. R. Andrew Clarke, who had paid great attention to the case throughout, and succeeded in arresting the bruit and pulsation after twelve hours' application. Hypodermic injections of morphia were given during compression. The day after the apparent consolidation of the tumour the patient was attacked with diarrhoea, and, when that had ceased, with hiccough, which caused him great distress, and would not yield to treatment. From this time he gradually sank, and he died at 5 A.M. on Monday.

The post-mortem examination, which was conducted by Mr. McCarthy, showed extensive mitral disease with large vegetations attached to the valves, a little basic pneumonia and pleurisy which had supervened shortly before death. A large aneurismal dilatation of the first part of the arch of the aorta, including also a portion of the transverse part, was found. The kidneys were fatty, and incipiently granular. In the spleen were signs of embolism. A good deal of serous fluid existed beneath the pia mater. On dissecting the parts at the bend of the elbow the brachial artery was found passing over the tumour, and dividing into radial and ulnar. At the point of bifurcation, on the under aspect of the vessel was a true aneurism, the size of a small bean. This had burst at some time or other, for it was found to communicate by a tiny slit-like hole with the tumour behind. The tumour was filled with coagulated blood of the consistence of red currant-jelly, but at its anterior part there was a mass the size of a bantam's egg of laminated fibrin, perfectly decolorised and free, in the blood cyst. The wall of the aneurism was formed by the condensed fascia in the intermuscular interspace.

It is probable that the false aneurism resulting from the rupture of the small true aneurism had been undergoing consolidation, and that the laminated fibrin which was the result of this process had been displaced, perhaps by excess of clinical inquiry, thus allowing blood to pass beyond it. The varying symptoms of the tumour were due to the blocking of the aperture at one time and its freedom at another. The inner side of the sac was very thin. On the radial artery was a second very small fusiform aneurism in process of formation.

A more serious mistake is to overlook aneurism altogether. The kind of cases in which this is apt to occur is where the aneurism is not in its usual position directly over the course of a large artery, but on one side, or seemingly altogether away from the artery. In my second case the aneurism of the popliteal artery was on the inner side of the limb, and when small and, possibly, without any very marked pulsation, it was regarded perhaps as an enlarged bursa connected

with one of the tendons. Another example of this kind came under my observation some years ago. I was asked to see a patient, and give my opinion as to the nature of a swelling which he had on the anterior aspect of the left thigh just above the patella. Whenever I am asked to look at a tumour, especially in the hospital, I always direct my mind in the first instance to aneurism, wherever the tumour may be situated. The case to which I refer might have been an enlarged knee-joint due to distension of the synovial pouch under the quadriceps tendon, or it might have been an abscess, for which it had been mistaken, and almost treated by incision. My own mind being already on the *qui vive*, and having an aneurismal bias, I at once examined for pulsation and bruit, and found both very plainly marked. It was an aneurism of the popliteal artery, which had come forward to the front of the limb, instead of remaining in the popliteal space. I mention this and the other cases, including one of my own, in which the diagnosis was either altogether at fault or uncertain, with the object of throwing out a useful hint to others. All the cases were under surgeons of reputation and experience, and when we find the great luminaries of surgery—men like Liston and others greater clinically than he—liable to be deceived, how much more the lesser lights which circle near them, and before them "pale their ineffectual fires." Then is suggested the practical question, How can such mistakes be avoided? My belief is that error would be much less common, if practitioners generally made it a rule in a case of tumour to answer the question first of all, Is this tumour an aneurism? and examine for pulsation and bruit as a routine exercise. When a tumour is over a large artery almost everyone instinctively makes the inquiry, but if it is away from it or at the side of it, or even behind it, or over a small artery, or if the mind of the practitioner is off its guard, very frequently abscess is suggested and aneurism is overlooked. Routine inquiry would obviate many mistakes. Then, if after inquiry the diagnosis be doubtful, it will be a good second rule to treat the case as an aneurism by measures which do not involve any detriment to the case if it should prove to be an aneurism after all. In situations where it is practicable, and in conditions under which it is not prejudicial to apply them, Esmarch's bandage, digital and instrumental compression, should be brought into requisition to throw light upon the case. The effect of Esmarch's bandage in emptying the sac of an aneurism, and rendering it flaccid, may remove any remaining doubts.

DIPHTHERIA AT ST. GEORGE'S HOSPITAL.

By T. WHIPHAM, M.B.,

PHYSICIAN TO THE HOSPITAL.

(Concluded from p. 650.)

CASE 5.—On April 14th, 1880, Alfred A—, aged one year, was admitted, under the care of Mr. Pick, into the Drummond ward (on the next floor and immediately above the Queen's ward, in which the patient Annie B— died on the morning of the 25th) on account of an old fracture of the femur.

This child was noticed by the nurse to be ailing on the evening of April 25th. Next day it was much worse, and considerable swelling was observed on both sides of the neck, and of the parts below the angles of the lower jaw especially. The throat was freely and frequently sprayed with a solution of sulphurous acid (1 in 40), and eight ounces of port wine were ordered, with as much milk as it could take; the child refused beef-tea. The nurse reported that it would not drink more than three-quarters of a pint of the milk during the day.

On April 27th, symptoms of asthenia became hourly more manifest, and he died at 2.15 A.M. on April 28th. The temperature was not observed, and no urine could be obtained for examination. No post-mortem was permitted, but Mr. Shield, the house-surgeon, examined the mouth after death, and found the fauces and tonsils covered by diphtheritic membrane.

It was subsequently ascertained that the mother of this child,

who was with him during his fatal illness, was afterwards attacked with diphtheria, but happily recovered. His nurse-maid, who was admitted with him into the hospital, and who nursed him, complained of sore-throat on the day of his death. She had a severe attack of follicular tonsillitis, and in a few days was perfectly convalescent. No false membrane existed in her case, nor had she any symptoms of diphtheria.

With a view of tracing if possible the origin of the disease in the case of the C— children, I applied to my colleague, Dr. Barclay, medical officer of health for Chelsea, who informed me that two deaths from diphtheria were reported to him as having occurred on January 29th and February 14th in Victoria-yard, which is distant about half a mile from King-street, but since the latter date he knew of no fatal case of the kind until April 19th, when the C—s were attacked. Dr. Barclay also informed me that on the cases being reported to him he at once made inquiries at the school; no children were known to have had diphtheria; nor have any of them been subsequently affected. By the kindness of Dr. Barclay I accompanied him on May 7th and inspected the house No. 22, King-street. We found the C—s occupied two rooms on the ground floor, which were fairly clean and lighted by good windows, the house being one of the better class of artisans' residences, and the street of good width. They also had the basement floor, on which were two rooms—a kitchen in front and a small room behind it. In this small room, which contained by measurement 560 cubic feet, slept the four children and their uncle, a lad of about twenty; the window of this room, which did not close accurately, opened into an airy back yard. On the right (in the yard) was a water-closet, on the left was a zinc cistern with a broken wooden cover, and between the cistern and the water-closet was a drain, which on the occasion of Dr. Barclay's first visit was uncovered by the bell-trap. Many repairs had been executed previously to our visit on May 7th (for instance, a defective portion of the water-closet pipe, as mentioned below, had been cut away and replaced by new), but it was elicited from the occupant of the upper part of the house that the supply pipe to the water-closet had leaked for some time, and that in consequence the water supply to the closet had been, to say the least, very defective. The cistern itself was perfectly clean, and was so when Dr. Barclay examined it at the time of the outbreak; it contained no waste-pipe, and the supply appeared to be constant. There was one outlet from this cistern, which supplied the house by means of an ordinary tap, which was in good order. The pipe was then carried across the back yard, a distance of about fourteen feet, and terminated in the water-closet. Immediately outside the closet and just above the untrapped drain, which evidently came direct from the water-closet, was the leak above mentioned. We learned further that another family occupied the upper part of this house, but they all had escaped infection. The family of C—s were seven in number; the father and mother slept in the room immediately above that occupied by the four children and their uncle; and of these, three children were infected and died—one in the house and two in St. George's,—while the remainder of the family escaped.

As soon as these children were found to be ailing—i.e., April 19th or 20th,—the fourth, a boy, was sent to No. 8, King-street, on the opposite side of the street and some distance further down. On the evening of May 1st, a girl aged sixteen, daughter of the occupier of the house No. 8—who used to be away all day at her work, about a mile and a half distant, in a neighbourhood in which no diphtheria is known to have occurred,—complained of pain and swelling below the angle of the jaw on the right side, and on the evening of May 5th died of diphtheria. On these premises were two cisterns: one solely for the supply of the water-closet, and placed above it in the back yard; the other, a slate tank, which was used for the house, was in a back room the dimensions of which were greater than those of the small room in which the C—s' children slept. The cistern was a large one, and was raised on posts, so that the top of it, which was unprotected by any cover, was within about six inches of the ceiling. The occupier, who used the room as a carpenter's shop, informed us that about two years ago he tried to clean out this cistern, but that the deposit from the water had choked both the pipe to the kitchen and the tap; that he had experienced so much difficulty in clearing the pipe and tap that he had made no subsequent attempt to clean the cistern. No further defect could be discovered in the sanitary arrangements of this house, and the occupier assured us that no bad smells arose from the drain (trapped) leading from a sink situated immediately below the cistern.

Dr. Barclay, on May 7th, received notice of the fatal case in No. 8, King-street; and was further informed that from the grating communicating with the main drain at the top of the street, which was about a hundred yards from No. 8, but less than half that distance from No. 22, foul smells constantly arose, which annoyed the inhabitants of the street. At the time of our visit, however, the street had been well watered with carbolic acid, the smell of which overpowered everything else, and we were unable to detect any foul odour arising from the grating in question.

An important question arises in connexion with these cases—viz., as to the source of the infection. With regard to the patients in the hospital perhaps the most remarkable is that of the girl B—, who was in Queen's ward with pneumonia. The disease was presumably conveyed to her by the child E. C—, who lay in a bed nearly opposite for two hours and a half, on April 21st. In making this statement, however, it must be mentioned that a child came under Dr. Dickinson's care into Crayle ward, exactly opposite to the Queen's, on April 12th, and died next day of diphtheria, and that the two wards are in the charge of one head nurse. If the disease was conveyed to B— from Dr. Dickinson's patient, the period of incubation must have been at least eight clear days; if, on the other hand, she was infected by the child C—, the incubation period was very short—i.e., the child was admitted about noon, and B— passed a very restless night on April 21st–22nd, with return of her delirium, unconscious evacuation of fæces and urine, and this after having shown very decided symptoms of improvement in the earlier part of April 21st. In the majority of recorded cases the period of incubation of the disease was short, and the presumption, I think, is that the patient B— was infected by the child E. C—.

In the case of the child A. A—, who was attacked while under treatment in a surgical ward, it has been stated that this (the Drummond) ward was on the floor immediately above the Queen's ward, where the patient B— died on the morning of Sunday, April 25th, and that the child was noticed to be ailing on the same afternoon. It is therefore possible that the infection spread from the one floor to the other, but if so it is a noteworthy fact that no other patient in the Drummond ward took the infection. So far, however, nothing is proved by it, for instances are of frequent occurrence in which diphtheria attacks one or two persons only in the same house, all the inmates of which are in constant communication. The escape of the nursemaid of this child and that of the boy in the C— family, as recorded above, are cases in point.

There was, however, another possible origin of the disease in the case of this child. In the Princess ward, which is opposite to the Drummond, an extra night-nurse was in attendance on a special case, and during the illness of probationer S—, she was directed to take beef-tea, &c., to her, she being isolated in a room on the top floor at the opposite side of the building. During the night of April 24th and 25th this night-nurse at frequent intervals went backwards and forwards between the Princess ward and the room where the probationer lay. At 5 A.M. on April 25th she crossed the Drummond ward in order to fetch a pail from the scullery, and walked straight out of this ward again into her own ward (Princess), without stopping even to speak to anyone.

A third possible source of infection in the case of the child Alfred A— was suggested, and for a time accepted—viz., that probationer S—, after the death of the C— children, visited the Drummond ward, and so carried the infection with her. On careful inquiry, however, I learned that the probationer invariably went to her own apartment by the staircase on the men's side of the house (the Drummond ward being on the women's side); that on the night when the C—s died no one saw her on the women's side, and that there was no reason for her having departed from her usual custom of using the staircase on the men's side.

Further, the superintendent of nurses informed me that, to her certain knowledge, the probationer after leaving the bodies of the two children in the separation ward went immediately upstairs to her own room, and changed all her clothes. These she carried down by the same staircase to the disinfecting room on the basement, where they were locked up by the superintendent herself.

What, then, was the source of infection in the case of this child in the Drummond ward? Did the infection spread

upwards from the Queen's ward on the floor below, or did the night-nurse, who was in constant attendance upon the probationer, convey it to the child by merely crossing and recrossing the Drummond at 5 A.M. on April 25th? If so, the period of incubation must have been a matter of, at most, twelve hours; while the infection must have been conveyed by a person, who had been in contact with the disease, passing at some little distance from the foot of the child's bed. The present state of our knowledge of diphtheria forbids our denying such a possible source of infection. I cannot, however, but think it more probable that the disease was communicated by the patient B—, who died in the ward below on the morning of April 25th, and who showed symptoms of the disease two days previously. In confirmation of this theory it should be stated that both the Queen's and Drummond wards are at the north side of the hospital, and that the main staircase runs immediately outside the door of each. In the ordinary course of events the ventilation would be upwards from the Queen's to the Drummond. The doors of the wards in St. George's are always open; there would, therefore, be more or less direct communication between the two.

In this supposition I am borne out by a remark contained in an extremely interesting paper in St. George's Hospital Reports, vol. ix. p. 706, by Dr. William Ogle. "So far as my experience goes," he writes, speaking of contagion, "diphtheria requires, as a rule, subject doubtless to no few unexplained exceptions, a very much closer and more prolonged intercourse than other zymotic diseases." It is true, however, that his remarks apply to diphtheria "as it ordinarily presents itself in country places"; and he goes on to say that "the ordinary social intercourse between neighbouring cottages is seldom close and intimate enough to effect the transmission." Such being the result of the experience of one who has seen much of diphtheria, it seems far more probable that the child in Drummond was infected from the ward below, than that he contracted the disease from a nurse who merely crossed the ward at some distance from his bed.

Apart from the interest which is necessarily attached to the period of incubation in zymotic diseases, and which, so far as diphtheria is concerned, remains doubtful in these cases, any facts bearing on contagion are of importance. It may not, therefore, be out of place to call attention to the fact that probationer S—, who nursed the C—s, exposed herself unnecessarily during the two days on which she was in attendance on them, for by her own confession she was guilty of the folly of kissing them. On the other hand, the mother of the children, who was also in constant attendance on them, hung over them and, as I am informed, repeatedly kissed them, escaped. Further, probationer S— and another nurse occupied the same bedroom, and the two occupied the room together so late as the night of April 23rd, when the probationer was already suffering from sore-throat. Until Saturday at midday probationer S— took her meals as usual in the nurses' dining-room with her fellows. None of these took the disease.

We have also this fact before us, that of four persons who were in constant attendance on a most malignant form of diphtheria, none of whom were known to have previously suffered from the disease, two became affected while the other two escaped—i.e., 1st, probationer S— and their mother nursed the C— children, and both kissed them; of these two the probationer died, while the mother was unaffected. 2nd. The nursemaid and his mother attended the boy Alfred A—, and the mother contracted the disease, while the nursemaid had merely follicular tonsillitis. It would be manifestly absurd to attempt to generalise from one or two cases, but at the same time the above facts are remarkable as having a possible bearing on the question of idiosyncrasy.

The origin of the disease in the case of the young woman who died at No. 8, King-street is obscure. Three possible causes have been mentioned: (1) That she might have contracted the poison from the grating of the main drain, which emitted foul odour; (2) that the boy C—, who was removed to the house from No. 22 on April 20th, conveyed the infection; and (3) that the disease was due to the unsanitary condition of the cistern in the back room of the house No. 8. It is of course impossible to form any definite opinion as to which of the three possible causes was operative in this case; but probability attaches itself to the first. It seems unlikely that the boy C— conveyed

the disease, seeing that a period of eleven days elapsed between his removal to the house and the first symptom of diphtheria in the girl; moreover, the child himself escaped entirely. With regard to the third possible cause it must be noted that, with the exception of the girl who died, none of the inmates of No. 8, who all drank of the water from this cistern, contracted the disease.

The difficulty of tracing the origin of an outbreak of diphtheria in a large town is of course great, and much caution must necessarily be exercised in drawing conclusions under doubtful circumstances. So far, however, as the investigation could be carried, the facts seem to point to the origin of this outbreak in the inhalation of sewer gas in the case of the inmates of the house No. 22, King-street. The source of the infection at No. 8 is very doubtful, but the poison was in all probability derived from the escape of foul gas from the grating of the main drain in the street; or was possibly conveyed by the child of the C—s, who was was received into this house from No. 22, where his sisters were suffering from the disease.

I may add that Mr. William Keen and Dr. Buchanan, whose practice lies in the neighbourhood of these houses, have, in reply to my inquiries, informed me that they had no knowledge of the existence of any other cases of diphtheria at the date of this outbreak. Measles, however, had been very prevalent in the West-end of London since the previous Christmas.

The result of treatment in the above cases was most unsatisfactory. The disease was clearly of a very malignant character, and stimulating as the treatment was, it seemed utterly powerless in arresting the fatal effects of the poison.

Green-street, Grosvenor-square.

FIVE YEARS' SURGICAL WORK IN THE CARDIFF INFIRMARY.

BY ALFRED SHEEN, M.D.,
SURGEON TO THE INFIRMARY.

(Continued from p. 616.)

THE following table exhibits the whole of the cases of

DEATH AFTER AMPUTATION.

Part.	Age.	Sex.	Time after Operation.	Cause.
Both legs	31	M	Few hours	Shock
" " " " " "	38	M	21 days	Pyæmia
Upper 1st 3rd thigh...	18	F	24 hours	Shock
Mid-thigh	21	M	3 hours	"
Lower 1st 3rd thigh...	52	F	1 day	"
Mid-thighs (both)	40	F	9 hours	"
Lower 1st 3rd thigh }	60	M	1 hour	"
Mid-forearm				"

The injury in each case was the result of railway smash.

Of amputations during this period, I have had 35 for accidents, and 11 for disease. There have been 7 deaths amongst the former, and none in the latter class. From the annexed tables it will be seen that, of 5 amputations in the forearm and arm, all recovered; and of 9 amputations below the knee, all recovered, except two cases of removal of both legs, both of which died. Then there are 7 thigh amputations, with 4 recoveries and 3 deaths, all the deaths occurring within twenty-four hours. The list of traumatic amputations is completed by 2 compound cases, both of which died within twelve hours of admission. In the thigh cases all the recoveries were under twenty years of age. Excluding the minor amputations of fingers and toes (10), there are 7 deaths in 25 cases, or 1 in 3½. Classifying these according to age brings out the following results:—

Cases.	Died.	
Under twenty....	10	1 ... Or 1 in 10.
Under forty.....	8	3 ... Or 1 in 24.
Over forty.....	7	3 ... Or 1 in 24.

These results agree in the main with those published by Mr. Callender, Mr. Bryant, and others, except in the case of those from twenty to forty years of age, where my death-rate is much higher; but this may have been from accidental circumstances, and, indeed, taking the small number of cases here dealt with, such statistics can scarcely be said to be of much value one way or the other.

Mr. Bryant states that "amputations for *acute* suppurative disease are most fatal, and should only be undertaken when strong necessity exists." In case No. 32—D. B.—, aged eighteen, compound fracture of both legs—the left leg became gangrenous on the ninth day, with profuse suppuration; the temperature was 104.2°, and the pulse 140. Next day the pulse was 160, the temperature 104.4°, and the patient was suffering intensely. Amputation had been advised on admission, and it was only now, after earnest entreaty, that he consented to have the limb removed (without his father's permission, however), and the result was almost marvellous. The operation was done antiseptically at 3 P.M., with the temperature at 104°. At 9 P.M. the pulse was 134, the temperature 99.6°, and the improvement in the general condition of the patient was remarkable. For eleven days there was a good deal of discharge, from some failure, probably, in carrying out the details of the antiseptic treatment; but the patient was discharged, quite well, in a little over one month.

In almost all the amputations here tabulated, antiseptics in some form or other have been employed, the use of the drainage-tube being universal, as also Esmarch's bandage; in suitable cases silver wire or carbolic catgut sutures, and carbolic catgut ligatures in all cases. In those cases where the antiseptic system has been carried out (spray, gauze, &c.), I have been especially pleased with the results. In one case—a Syme's amputation for disease of the tarsus—terebene was used, the lint being kept constantly saturated with it, as suggested by Mr. Waddy. The operation was performed on August 16th, 1877. On the 22nd there was a somewhat disagreeable odour, and the dressing was removed for the first time on the 27th, when there was a slight discharge of pus. The temperature all this time was never higher than 99°. The terebene was then replaced by carbolic-oil dressing. From Sept. 6th to 8th the stump was tender, and there was an erysipelatous blush, with red lymphatics, and a temperature of 102° to 103°. Tincture of aconite, one minim every quarter of an hour four times, and then every hour, was prescribed; and the temperature was normal on the morning of the 9th, and remained so. The aconite was then given at gradually increasing intervals, and stopped on the 13th. On Sept. 20th there was a repetition of this state of matters, with, on the 21st, pulse 112, temperature 103°. Aconite was given as before. In the evening, pulse 92, temperature 100°; and on the 22nd, pulse 80, temperature 99.4°; evening, pulse 80, temperature 97°. In May, 1878, he had a capital stump, on which he could jump without any pain.

The "Carden" E. S.—(No. 10), aged thirty-two, in April, 1878, died in May, 1880, of phthisis. In the "Carden" W. S.—(No. 11), aged forty-eight, hæmorrhage came on a few hours after the operation, necessitating a reopening of the stump to search for the bleeding vessel; this was not found, but there was no further hæmorrhage. The popliteal aneurism was dealt with antiseptically, and the temperature was normal throughout, except on the evening of the operation, and next morning, when it reached 100°. The case of J. J.—, aged fifty-one (No. 5 of amputations for disease), was treated antiseptically; the temperature was normal throughout; there were four subsequent dressings; and the patient was up in eighteen days.

R. H.—(No. 32). There was some tendency to a conical stump, which was obviated by means of a loop of strapping, and a weight attached to this and hanging over the end of the bed.

T. M.—(No. 11). Drainage-tube and carbolic oil. No rise of temperature throughout.

W. S.—(No. 13). No rise of temperature.

G. H.—(No. 9). Amputation through metacarpal bones; thumb left.

R. H.—(No. 20). Styptic colloid and drainage-tube. On removal of styptic the line of incision was completely healed, and without the slightest disturbance of its edges.

W. P.—(No. 10). Amputation through wrist, leaving the thumb, and obtaining a single flap from the palm.

D. B.—(No. 32). Antiseptic. No constitutional symptoms.

T. R.—(No. 12). Drainage-tube and styptic colloid. Styptic removed on the fourteenth day. Wound partially healed. All five catgut ligatures intact except one, which had cut through the tissues, but was still whole. Five days after, "sutures giving way."

T. R.—(No. 27, "Carden"). Antiseptic. Eight subsequent dressings. Detained on account of slow healing of superficial granulating surface. Slight bagging of pus on

the eighteenth day in this case, and the temperature went up for one day, but was otherwise normal.

Some years ago, at one of the Societies' meetings, a discussion took place on the value of different kinds of ligatures, which, I think, was called the "battle of the ligatures." If my memory serves me right, the catgut ligature came in for a pretty fair amount of condemnation, from the liability, as was stated, of secondary hæmorrhage following its use, and from a fear of its slipping and a dread that it might melt away before it had served its purpose. I believe such fears to be mythical. I have shown that a carbolic catgut suture will remain intact for a number of days, and I have never seen a case of secondary hæmorrhage following its use during the period covered by these reports. It seems to me to answer all the purposes of the best silk ligature, and has none of its disadvantages. We have used it now, exclusively, for the last ten years.

Besides the amputations, I have had seventy-three *operations of various kinds*, without, excluding the cases of strangulated hernia, a single death. The cases of hernia offer another painful illustration to the many now in existence of what the late Mr. Callender called "too late operations for hernia." All of them except one died, and it will be noted that the shortest time during which there had been symptoms of strangulation previous to admission was thirty-six hours. Some of these cases were already under medical treatment, and the delay is, therefore, all the less excusable. It is really difficult to write calmly about such cases. One case may be worth recording as offering a few points of interest.

J. K.—, sailor, aged thirty (No. 71), admitted Sept. 9th, 1878. In March last, whilst helping to lift a boat overboard, he ruptured himself, but felt no pain or inconvenience till three or four days after, when he had much pain, which was relieved by a linseed-meal poultice. He resumed work in a few days, and felt no further inconvenience till Sept. 5th, when he had pain in the lower part of the abdomen and in the course of the right inguinal canal. This increased on the 6th and 7th, and on the 8th he took to his bed and sent for a doctor, who endeavoured to return the hernia, and was under the impression that he did so; he subsequently gave a large dose of castor oil, which had no effect. The man, not getting any better, was admitted into the Infirmary at 6 P.M. on Sept. 9th. On admission the right scrotum and inguinal canal were much larger than the left, hard, thickened, tense, and painful to the touch. No impulse on coughing; hiccough. Pulse 100, full. No sickness or *anæsthesia*. He states that the bowel has never gone back since the accident. At 7.30 P.M. I manipulated the parts, under chloroform, but without any effect beyond some reduction of the tension, after which the patient expressed himself as being somewhat relieved. Ordered an enema and an evaporating lotion.—10th: Bowels relieved copiously three or four times. Hiccough has ceased. Pain less, though patient still complains of considerable pain over the tumour and inguinal canal. Pulse 96; temperature 101.4°. The case being somewhat obscure, after a consultation, I proceeded to operate, and in the course of the operation there were two points worthy of notice. When, by the escape of serous fluid, which was yellower than usual however, I thought I had opened the sac, I was rather put out by the appearance of the parts exposed, which did not resemble bowel or thickened omentum. On examining more carefully, it was found the fluid came from a small cyst which had been opened. I proceeded with the operation, and found the sac a quarter of an inch thick, empty, but giving out an excessively disagreeable smell, its internal surface being greenish and sloughy. The finger could be passed into the abdominal cavity by the canal. After the dressing a quarter of grain of morphia was given hypodermically; at 9 P.M. twenty grains of chloral. Hiccough troublesome. Has been sick once. Pulse 96; temperature 100.4°.—11th: Passed a fair night; bowels relieved once; sick once; constant hiccough, which ceased at 10 A.M. He gradually sank, and died at 9 P.M.

Necropsy.—Abdomen: Loop of small intestine, ten or twelve inches long, in right inguinal region, black in colour, with small blebs containing air on its surface, manifestly gangrenous. The gangrenous portion of the bowel had its convexity towards, and approached, the internal inguinal ring. The intestine was wholly within the abdominal cavity, and the gangrenous portion was adherent to other portions of the neighbouring bowel by a limited effusion of lymph. The gangrenous intestine, when divided, was found

to be much thickened. The sac of the hernia was throughout much thickened, and contained one or two cysts on its outer surface.

The case of elephantiasis labium (No. 52) occurred in a married woman, formerly a prostitute; it had been some years growing, and involved both sides. At the time of the operation she was seven to eight months pregnant. The

tumours were removed by the knife, and weighed two and a half pounds. Labour came on at the full time, before the wound had healed; a living child was born, and the woman recovered quickly.

During the five years covered by this report, no uniform system of dressing wounds after operations has been carried out, as will be seen from the tabulated list of cases. The

drainage-tube has been invariably used where required, and silver wire or carbolised catgut sutures.

A. R—, aged thirty-seven (No. 29).—Cystic tumour of the breast. The edges were brought together by catgut sutures supported by broad pieces of strapping, and sponges, which had been soaked in carbolic-acid solution (one to twenty) for twenty-four hours, applied as a dressing,

these being kept in position by a bandage. A drainage-tube had been previously inserted in the wound. Fresh sponges were applied in two days, and in three days more, boracic ointment. All the sutures held till the seventh day, when one gave way. There was but very slight discharge, no bad odour, and the temperature was normal throughout.

M. G—, aged thirty-five, cystic tumour of breast (No. 28).

Incision six inches long. Drainage-tube, catgut sutures, and styptic colloid dressing. Dressing removed in thirteen days, and whole line of incision soundly healed except at its extreme points. Temperature normal throughout, except on one day, when it was 101° 8'.

M. W—, aged fifty-eight (No. 30).—Same disease and similar treatment. Styptic removed in nine days, and one-third of line of incision found healed. Temperature normal throughout, except on one day, when it was 100° 2'.

(To be continued.)

PAUSES IN RESPIRATION.

By WILLIAM O'NEILL, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE LINCOLN LUNATIC HOSPITAL, ETC.

SOME interesting cases which have lately been under my observation induce me to say a few words in reference to pauses in breathing. A pause in breathing is the most striking feature in that peculiar irregular breathing, marked by a series of ascending and descending respiratory acts, occasionally met with in some diseases of the heart and brain, and which was first noticed and described by the late Dr. Cheyne of Dublin, and subsequently by the late Dr. William Stokes of the same city. A case of "cerebral breathing" with nearly these characteristics presented itself to me a short time ago. The patient, who was suddenly attacked with apoplexy, became almost immediately comatose and paralysed on the right side. On the second day of her illness, on four or five occasions of about an hour's duration, the breathing assumed this form. The inspirations, which were of a blowing, almost of a whistling character, were about seven ascending and seven descending, the latter ending in the pause, which was usually about fifteen seconds in length.

What I wish, however, more especially to say is that the respiratory pause may be well marked, although the ascending and descending breathing acts may be more or less deficient, or even absent. Whether or not all those kinds of abnormal respiration which have a pause for their central phenomenon or symptom should be included under the category of Cheyne-Stokes respiration I am not prepared to say.

A lady who has suffered for several years from chronic bronchitis, emphysema of the lungs, great irregularity of the pulse, and hypertrophy, with dilatation of the right side of the heart, was attacked with an acute exacerbation of the chronic pulmonary affection in December of the past year. Edema of the ankles, which was generally present, rapidly increased, and in a few days the dropsy extended to the waist. After this the patient was unable to lie down, and, although very drowsy, she was afraid to go to sleep, for the moment she closed her eyes in sleep the breathing stopped, and was only renewed on her waking, which was generally after an interval of from twenty to thirty seconds. The apnoeal state, followed by a succession of inspirations, gradually increasing in force, and ending in the ordinary dyspnoea of the patient, were the phenomena present in this case. The ascending series of inspirations were present, but the descending were absent. It would appear that the moment the watchful and controlling care of the will was withdrawn from the respiration by sleep the breathing stopped, from some cause or other acting on the medulla oblongata, and which had been kept in abeyance during the patient's waking moments; and respiration was, I think, only renewed by the intensity of the stimulus of the *besoin de respirer*, which roused her to the urgent necessity of breathing. The immediate cause of the pauses was temporary, for as soon as the chest symptoms began to improve and the dropsy to subside, so did the pauses begin to pass away.

A case almost similar to the preceding came under my care in 1878. The pauses were perhaps longer and the series of inspirations more distressing. So frightened was this man of the stopping of his breathing that for a few days before his death he kept his wife by his bedside in order to prevent him falling asleep.

But, as I have said before, the respiratory pause may be present in a case without any other apparent deviation from the normal breathing. The patient may be respiring tranquilly and regularly when the pause occurs. He ends the act of breathing with an expiration, remains in a state of apnoea for a shorter or longer time, resumes breathing with an inspiration, and then goes on breathing naturally till another pause takes place.

I have seen two or three examples of this kind of respiration. Not long since I had a well-marked case of it under my care. A patient sixty years of age, who had always been a strong man, began to fall off in health and strength about ten or twelve months previously. His appetite failed, he gradually became thinner and paler, and suffered considerably from pains in his legs and soles of the feet. Latterly he complained of breathlessness and palpitations of the heart on exertion, of oedema of the ankles, of cough with a troublesome secretion of mucus in the throat, and of great depression of spirits and loss of sleep. On examination the lungs, kidneys, and other organs of the body were healthy, with the exception of the heart, which had a weak impulse and showed some evidence of enlargement. There was no bruit to be heard in the præcordial region, but the first sound of the heart was short and rather indistinct, the second comparatively loud and clear. About ten days before this patient's death he "fainted" on rising in the morning, but when I saw him a short time afterwards he had not only recovered from the attack but seemed inclined to make light of it. That night he was delirious for the first and last time. The next day he was better and sitting up, but on the following day I noticed that he paused for a few seconds in breathing. The pauses, which were the only deviation from natural breathing, and which at first occurred every twenty or thirty minutes, gradually increased in length and frequency, and when at the longest their duration ranged from eighty to ninety seconds. This almost unprecedented length of the respiratory pause showed the large amount of carbonic acid necessary to accumulate in the capillaries of the lungs in order to produce stimulus sufficient to set the breathing going. The respirations in the intervals of the pauses were about eighteen in the minute, the pulse 80 in the minute, and the temperature of the body 98°. The pauses occurred both when the patient was asleep and awake, with, I believe, equal frequency, and were generally accompanied with more or less insensibility. The nurse and relations thought the pauses were the longest at night. I have seen the patient get out of bed with the assistance of the nurse to go to the night-chair, and on his way attacked with one of these trance-like seizures. I have shaken him and spoken loudly to him in order to induce him to resume breathing, and although he moved his lips and made a slight effort to speak in response yet he did not respire for more than a minute. I have often felt the patient's pulse and examined his chest during the states of apnoea, but neither the strength, regularity, nor frequency of the pulse, nor action of the heart, was affected by them further than that I sometimes thought that the last eight or ten beats of the pulse were a little weaker, and a little more hurried than those which had preceded them. The chest during the pauses was quite motionless, and nothing could be heard by auscultation but the sounds of the heart strangely reverberating through it. Accompanying the apnoeal attacks was a gradually increasing aphonia which ended in a mere whisper, and a peculiarity of swallowing. The patient would take a mouthful of fluid, wait for a minute or two and then gulp it down; the action of swallowing generally caused some coughing. The cough and secretion of mucus into the patient's throat during the early part of his illness were a source of great annoyance to him, but, from first to last, there was no appreciable inflammation or congestion of the lungs. I noticed that during the patient's waking hours he hardly ever winked. The pupils of his eyes were apparently normal, the conjunctivæ were congested, and occasionally he complained of indistinctness of vision, and of flashes of light before his eyes. All through his illness, excepting when in a state of apnoea, until about six hours before his death, he was sensible, and knew his relations and those about him. He sometimes complained of slight headache, and of uneasiness in the region of the heart and stomach. The pulse was regular, although weak, and never varied from 80 in the minute until the end was drawing near, when it became very feeble and quick. The breathing also towards the close was more rapid, the pauses were more frequent and shorter, and the temperature never exceeded 99°.

Although no post-mortem examination could be obtained, the pauses were, I think, the result of some lesion which not only affected the medulla oblongata, but also other parts of the nervous centres, as evidenced by the loss of voice and the difficulty of deglutition. The patient suffered most probably from fatty degeneration of the heart; and the fainting fit, which seemed to have ushered in his fatal illness, may have been one of the cerebral attacks sometimes seen in fatty disease of the heart. When I saw the patient soon after the fit I thought it might have been caused by embolism, and the subsequent symptoms lend some weight to that hasty opinion.

It has been said that hydrate of chloral is a very useful remedy in Cheyne-Stokes respiration. It so happened this patient had been taking hydrate of chloral when the respiratory pauses came on, and it was fully tried, but without any good result. The patient was ordered plenty of nutriment, and medicines of various kinds were prescribed; but the medicine from which he derived the greatest benefit was dilute nitric acid in a bitter infusion. This mixture sustained his strength, freed him from the troublesome throat mucus, and quite subdued the cough, thus rendering him more comfortable in his latter days. I tried the inhalation of nitrite of amyl with persistency in this and a similar case, but unfortunately with no apparent benefit. The nitrite of amyl inhalations may, however, be of use in Cheyne-Stokes respiration proper, where the ascending and descending rhythm of inspiration are well marked. The inhalations were of great use in a case of this kind which I had under treatment more than five years ago. The patient suffered from intense renal dropsy with great orthopnoea, the breathing during the last few weeks of his life assuming well-marked Cheyne-Stokes respiration. This patient derived much comfort and relief from time to time from the inhalation of four or five drops of the amyl. On several occasions it restored and reinvigorated the breathing when it was about cease.

The respiratory pause, it would seem, may be the result of either functional derangement or organic disease, but evidently more frequently the result of the latter. In these cases I am of opinion that treatment, no matter how judicious, is of little or no avail; for when this symptom sets in it is generally the precursor of dissolution. I might add that it is a most impressive symptom, and requires to be only once seen to be for ever remembered.

Lincoln.

A CASE OF TRUE EASTERN LEPROSY.

By JAMES STARTIN, M.R.C.S. ENG., &c.

TYPICAL cases of true Eastern leprosy of the anæsthetic variety are rarely seen in this country. The notes of the following case may be of much interest to the profession, especially as there is, at the present time, a considerable controversy going on as to the true etiology of the disease in this country and abroad, some authorities ascribing the cause to the eating of bad fish.

E. McG—, aged forty-six, a native of Derbyshire, went out to India in 1858 at the age of twenty-three years with his regiment, and he remained out thirteen years. His father and mother are both natives of Ireland, and there was no family history of syphilis or skin disease. The patient stated that he himself contracted syphilis whilst in India, and was cured there. He was vaccinated three times in India from natives, and twice at home, and he has not had small-pox. He came home to England about ten years ago. He then noticed, as he was on his way home, a slight mottling of the skin, and felt a numbness in the hands and arms, and a feeling of pricking as of pins and needles in the fingers and arms. He states he had plenty of food and very little fish, a few sardines and other tinned fish, but this he had only occasionally, and it was fresh. But he had no fresh vegetables for some years. He had eaten a good deal of Indian corn made up as food at one time or another, and he does not attribute his disease to the eating of bad fish, as he says he had so little fish of any kind. He had had several bad attacks of ague and fever, which he said much weakened him, and he was often exposed very much to the climate.

When he first came under my notice he was covered with an eruption of brown maculæ or spots about the size of a sixpenny-piece, very slightly raised above the level of the

surrounding skin. He had also patches of brawny brownish skin quite insensible to a prick of a needle; in their centre, in different parts of the body, on the anterior surface of the bend of the elbows and forearm, were patches about eight inches long and three broad, also on the side of the neck, face, and ears, but smaller in size. The cutaneous nerves of the arm and forearm and the ulnar nerve could be seen and felt as tense and swollen cords, knotty and hard to the touch—a very characteristic and diagnostic feature in this disease, and being very well-marked in this case. He had also a tuberculous leprosy-looking sore on the left leg on the inner side, about four inches below the knee-joint, and he had also a brown anæsthetic patch over the left knee. The next important feature of the disease was that of considerable wasting of the muscles between the thumb and index-finger and the intermetacarpal spaces, and he lost the power of adducting or closing his fingers, or even of holding anything in his hands. A pail of water he would let fall from want of power to keep his fingers closed. The outer side of the little-finger and hand was quite insensible to puncture with a needle. The patient complained of feeling much depressed at times. The mucous membrane of the mouth, tongue, and lips was much affected with tuberculous patches, and very tender and sore at all times. At this period of the case I had a drawing taken of the patient, showing most of the features described. With regard to the treatment, I must say he has very much improved under the continued doses of chaulmoogra oil, taken first as an emulsion; then, as it returned very much, the capsules, of which he took as many as twenty a day; and he well rubbed the oil into the skin; he also took large doses of quinine, which he said he felt much better for.

He has now regained the use of his hands, and the anæsthetic patches are losing their insensibility, and the patient tells me that he feels much better and stronger, and the eruption is disappearing.

Now, with respect to diet, I ordered him, whilst he was in the hospital, a good diet, unstimulating, with plenty of fresh vegetables, which he much enjoyed, having had so little of them. As to the influence of bad fish as a common cause of origin of this disease, I confess I am very sceptical, this case in point of fact (and there could not be a more typical case, as was said by Sir Joseph Fayrer, Mr. Erichsen, Mr. Hutchinson, and several other eminent members of the profession, to whom I had the pleasure of showing it at the Medical and Chirurgical and Pathological Societies) could not be possibly ascribed to the eating of bad fish, for he had none. But I do firmly believe that the want of fresh vegetable food, and continued attacks of fever and ague destroying the nerve vitality, to be the principal causes of this case, and of others of leprosy. Most of the cases of this terrible disease occur in India, and, as I am reliably informed, the natives live almost on nothing, or whatever they can get, and it is amongst this class the disease is most prevalent. What can the supporters of the fish theory say to the fact that the natives on the borders of the great desert of Sahara never eat fish, and yet they get leprosy in its worst forms. And, again, the natives of Rawal-Pindi in the Punjab in India, and the natives who dwell on the Naga Hills in Assam, do not eat fish, and yet they get it too. Now the natives or the "Nuggs," who live in Arakan, live on fish, yet leprosy is seldom if ever seen among them. These and other important facts which I have elicited from reliable sources, from men who have seen many years' active service among the natives of India and Northern Africa, completely upset, in my opinion, the theory of the eating of bad fish as the origin of true leprosy. Neither do I believe leprosy to be a contagious disease.

Sackville-street, W.

DECALCIFIED BONE DRAINAGE-TUBES.

By SURGEON SHIRLEY DEAKIN, F.R.C.S. ENG., I.M.D.

IN an Indian station, far removed from surgical instrument makers, drainage-tubes are not often procurable, gutta-percha tubing even not being included among the articles of the small local store which does duty for a shop. Though native workmen are clever enough at copying an article from a pattern, they are very stupid in working from an engraving. Further, as regards bone drainage-tubes, all respectable Hindoos have serious caste objections to touching bones, so

that there might be difficulty in getting a workman to turn bone tubes after the method suggested by Dr. Neuber of Kiel, as given in MacCormac's "Antiseptic Surgery."

In the long bones of the limbs of poultry and small birds I have found capital drainage-tubes ready turned to hand. The bones, collected by the cook and well boiled to free them from the soft parts, are soaked for about ten hours in a mixture of one part of hydrochloric acid and two parts of water. Immersed for this time, they become sufficiently soft and flexible for use, and to be cut with ordinary scissors. The ends of the bone are now cut off with a pair of scissors, and the medullary canal well cleaned out with a thick wire or rat-tailed file. The bone tubes should then be boiled in a 5 per cent. solution of carbolic acid, to which some borax—an antiseptic procurable in every bazaar at a very cheap rate—has been added. The tubes are to be kept in a 5 per cent. solution of carbolic oil. If the ends of the bones are cut off with bone-nippers before being decalcified, they are very liable to split. If soaked too long in acid, the walls of the bone tube become too soft and gelatinous, and the lumen is liable to be closed by the pressure exerted by the edges of the wound into which the tube is inserted.

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

SEAMEN'S HOSPITAL, GREENWICH.

TWO CASES OF OBSCURE NERVOUS DISORDER.

(Under the care of Dr. RALFE.)

THE two following cases are of considerable interest. As no post-mortem examination was required in either case, the nature of the pathological conditions which were the active factors in the production of the symptoms described can only be conjectured. In the first case Dr. Ralfe thought the lesion to be possibly of a tubercular nature; the improvement that occurred under treatment with iodide of iron strengthens this supposition. In the second case the question may be raised whether the trembling was due to an imperfectly developed chorea following rheumatism, or whether the case should be regarded as an attack of acute spinal sclerosis passing gradually into a chronic form. The reports of the two cases are drawn up from full notes taken by Dr. H. Fonnartin, the house physician.

1. *Case of unilateral muscular atrophy; sudden supervention of delirium with epileptiform convulsions; improvement before discharge.*—W. D—, aged eighteen, from the training ship *Arethusa*, was admitted on May 15th. The family history was unknown. Among previous diseases he had had epistaxis every summer for years, and rheumatic fever (?) during five days two years ago. The patient attributed his actual illness to over-fatigue when tramping some months back, and a fall on the left leg about the same time. He said, however, he had only noticed his present condition six weeks.

On admission it was noticed that the patient could only imperfectly close his mouth, the left commissure remaining gaping. The tongue deviated towards the left side, the left half being also very much shrunk and atrophied. Speech was somewhat indistinct. There was cephalalgia, or rather left hemicrania, and there was numbness, loss of power, and muscular atrophy of the muscles of the left half of the body, the wasting of the left interosseous muscles of the left hand and the muscles of the calf of the left leg being most marked. He had constant pain in the left popliteal region, with semi-retraction of the flexor muscles of the leg on thigh, all attempts at extension or flexion being attended with much difficulty and pain. The walk was very unsteady, but exhibited no sign of ataxy. He had had no rigor, except one three mornings before admission. No vomiting or constipation. There was no history of infantile paralysis. Both

lungs were full of bronchial râles, especially on the left side. There was a noisy, loudly-barking cough, suggestive of paralysis of left vocal cord. The spasmodic condition of the patient prevented complete laryngoscopic examination. The urine was normal. Temperature was normal, and continued so throughout, except occasionally before and after the paroxysms hereafter described, when it rose to 99° F. Ordered ten grains of iodide of potassium, thirty of bromide of potassium, and thirty drops of the syrup of iodide of iron, with infusion of quassia, three times a day; two teaspoonfuls of cod-liver oil three times a day.

On June 25th it was noted that during the last four days the pain in the popliteal region had been worse, otherwise the patient was better. The cough was still troublesome. The appetite was improved, the patient was gaining flesh, and slept well. The lingual hemiatrophy was less marked, the speech more distinct, and the mouth was less deviated.

On the 30th he suddenly became restless, then delirious, with pupils dilated. A draught containing one drachm of bromide of potassium quieted him for some hours; towards morning he became unconscious and comatose, with constantly recurring clonic convulsions; then gradually he became delirious, imagining himself on board the *Arethusa*, working the rigging, and surrounded by negroes. After a time there was an intermission, and he became partially conscious, answered questions, swallowed liquids, said he saw everything black and that there was a mist before his eyes. Then he again became comatose, the convulsions re-appeared, followed by violent delirium, then an intermission, and so on throughout the day. Ophthalmoscopic examination was impracticable.

The attacks have continued since last note, but on the night of July 2nd he slept well, and next morning he was quiet and reasonable. Still he complained of mist before his eyes, but said it was less. Continued quiet till July 5th. In the afternoon of this date he became violently delirious, and had epileptiform convulsions. He had frequent similar attacks till July 18th, occurring usually toward evening, with quiet mornings. Then from July 18th till August 1st a quiet period occurred, with occasional occipital headache.

On August 2nd he had another seizure, with clonic convulsions, followed by delirium, succeeded by a quiet period till August 17th, when at 5 o'clock in the evening he became violently delirious; thirsty, and vomiting all he drank. He continued in this state till 5 P.M. the next evening (Aug. 18th), when he became unconscious, the vomiting, however, still continuing. On August 19th he was perfectly conscious, had no headache, and no vomiting, though there was slight nausea and pain at epigastrium.

From this date he made steady improvement. About the 23rd he began to get up every day, and on the 30th he was able to dress, stand, and walk about unaided. His walk was much improved compared with the tottering gait noticed on his admission. The cough had disappeared, the appetite was good, and sleep excellent. The lingual atrophy and wasting of the left leg were less marked, and the atrophy of the interosseous muscles of the left hand was not so apparent. He had gained flesh, was free from pain, and his eyesight was perfect. He left the hospital on a week's leave, but did not return. The treatment throughout, when he could be got to take medicine, consisted in bromide of potassium and syrup of the iodide of iron.

2. *Case of pyrexia accompanied with violent delirium, followed by tremulousness which persisted after convalescence was established.*—H. H—, aged twenty-four, able seaman, native of Finland, was admitted on April 23rd. His last voyage was from Haiti, where it was stated he contracted, seven months previously, fever, which lasted only one week. No further history could be obtained.

On admission the patient was so violently delirious that he had to be tied down in bed. The skin was hot and dry, but sometimes he broke into a profuse sweat; face flushed. Evening temperature 103.4°. Ordered ten grains of bromide of potassium and five grains of bicarbonate of potash, in infusion of quassia, three times a day.

On the 25th he was still delirious. There was marked pericardial friction. Urine clear, alkaline; no albumen; chlorides abundant; sp. gr. 1034. Constipation. Ordered enema of olive oil. Temperature: morning, 104.1°; evening, 102.4°.

On May 1st he was conscious and complained of pain at the præcordium. The heart sounds were weak, rapid, and distant. There was still some præcordial friction; the area of præcordial dulness was not increased. He was still con-

stipated. Since the delirium has disappeared an excessive tremulousness affecting his tongue, upper and lower limbs, has set in; this was produced only by voluntary movements, and the shaking was increased by a repetition of the same movements. The tremor seemed to be composed of a succession of very limited and rapid clonic spasms, the movements, however, did not approach to the extensive and disorderly actions observed in chorea. Temperature: morning, 103.2°; evening, 98.4°.

On the 10th the tremor still continued very excessive. Since the previous note pneumonia of the base of the left lung has developed. Constipation persistent. Temperature: morning, 100.2°; evening, 103.4°.

On the 18th the tremor was unaltered. The pneumonia was subsiding; pericardial friction no longer heard; constipation still persistent. Bedsores are forming over the sacrum and trochanters. Temperature: morning, 102°; evening, 98°.

On the 28th the tremor continued as violent as ever, although the patient in other respects was making satisfactory progress. The temperature, however, still remained high, and fluctuated considerably; in the morning it was 101.1°, and in the evening 103.2°. Up to this time he had been taking bromide of potassium with salines; to-day he was ordered fifteen grains of salicylate of potash every four hours. Still troubled with constipation.

On June 13th the tremor had not been influenced by the salicylate treatment, though the temperature had steadily declined and did not fluctuate so widely. Temperature in the morning 100°, in the evening 100°. The salicylate was discontinued, and half-drachm doses of bromide, three times a day, substituted.

The temperature became normal on June 18th, and remained so. The excessive trembling continued, however, till the middle of July, when an improvement was noticed first in the lower limbs, and he was shortly able to walk. The improvement, however, as regards the tongue and upper limbs was very gradual, and even on Aug. 5th, when the patient demanded his discharge, was still marked. In all other respects he was well and strong, he had gained flesh, the lung mischief had cleared up, and there was no murmur over the præcordium. It may be as well to mention that during the attack there was no pain or swelling in any joint, nor did the sweating continue after the first week.

SUSSEX COUNTY HOSPITAL.

LITHOTRITY AT ONE SITTING.

(Under the care of Mr. JOWERS.)

For the following notes we are indebted to Dr. John C. Uthoff, house-surgeon.

J. B—, aged sixty-two, a flyman for many years, was admitted Sept. 1st, 1880, suffering from symptoms evidently pointing to stone in the bladder. These symptoms have been gradually coming on for about two years. He was of medium stature, fairly healthy in appearance, with a florid countenance. The urine, when first examined, contained blood and albumen; slight deposit, showing microscopically a few uric-acid crystals; acid in reaction, sp. gr. 1018. The condition of urine varied, being on some days the same as above, on others alkaline, fetid, and containing much mucus, but no blood. The lungs, heart, and abdominal viscera were healthy.

On being sounded a stone was detected, which gave the impression of being a large and hard one. It measured slightly over two inches in its longest diameter, and about half an inch in its smallest. During the time he was in the hospital before being operated upon the urethra was dilated by catheters until a No. 16 could be passed without difficulty. This was done in order to accustom his urethra to the passage of a large instrument, and so of the lithotrite.

On September 17th chloroform mixture was administered and lithotritry performed. The stone was crushed without difficulty. The lithotrite was introduced six or seven different times, Thompson's (modified Bigelow), washing-out apparatus being used between each of the crushings. The whole operation lasted about an hour and a half. A morphia suppository was placed in the rectum, and the patient was wrapped in hot blankets, and put to bed with hot-water bottles to feet and body.

He recovered with scarcely a bad symptom. The scalding on micturition was but slight. He had only one slight

shivering the day after operation. The slight tenderness of the abdomen following the operation soon passed away, and by the ninth day he was all but well. On the twelfth day after the operation he got up, and on the sixteenth was discharged well.

The stone was entirely composed of uric acid, and the débris removed after the operation weighed just a little under the ounce.

TOXTETH PARK WORKHOUSE INFIRMARY.

HÆMORRHAGE INTO THE SPINAL CORD.—ANEURISM OF THE ARCH OF THE AORTA.

(Under the care of Dr. LYSTER.)

For the following notes we are indebted to Dr. Charles Woods, resident medical officer.

CASE 1. *Hæmorrhage into the spinal cord.*—Mary G—, aged sixteen, was admitted on January 7th, 1879, suffering from paralysis of the left leg below the knee, with œdema and anæsthesia, contraction of the leg on the thigh and the thigh on the abdomen, with extension of the foot. The girl was strong and healthy-looking, and stated that the paralysis came on suddenly about two months before as she rose from a chair on which she had been sitting for a few hours. The temperature of the body was normal, the faradaic excitement of the paralysed limb was intact, there was no local tenderness along the spine, and the only pain complained of by the patient was of a neuralgic form, shooting along the fibular nerve. In a few days large bedsores rapidly began to form (in spite of the utmost care and attention), followed by retention of urine, to relieve which a catheter was passed, the introduction of which invariably caused spasm. Incontinence of urine supervened, with paralysis of the rectum, and finally death from exhaustion on February 28th. The urine was alkaline, and free from albumen.

At the necropsy, made five hours after death, the spinal cord was removed, but was very soft, and when a transverse section was made the grey matter oozed out like reddish serum. Opposite, about the ninth dorsal vertebra, a clot about one inch long and a quarter of an inch wide, was seen lying lengthways in the posterior and lateral portion of the cord. Around it the cord was broken up, and it was surrounded by a wall of jagged tissue stained with blood, so that there was obliteration of the sound tissue round the clot, from which several processes emanated.

CASE 2. *Aneurism of the arch of the aorta pressing on the trachea and right bronchus.*—Mary M—, aged forty, charwoman, came under notice on the evening of Aug. 22nd, suffering from severe dyspnoea, accompanied by a whistling sound on breathing and coughing. The patient complained of a sense of constriction, and a difficult cough followed by the expulsion of some frothy mucus, and had a careworn, anxious appearance. The sterno-cleido-mastoid muscles were contracted and formed two rigid pillars on each side, whilst the chest walls were expanded to their fullest. On examining the chest the left side was resonant, but there was dulness on percussion over the right, which was retracted. No breath-sounds were to be heard over the right side, and but feebly over the left. The heart-sounds were very weak, and could barely be heard. It was concluded that the case was one of aneurism pressing on the trachea, and the patient was kept quiet and antispasmodics administered. The patient, however, died rather suddenly on the morning of the 24th.

At the necropsy, on raising the chest walls, the left lung was found overlapping the heart, but the right lung was not seen. The pericardium was firmly adherent to the heart and to the right pleura, which was completely united to the right side, tying down the right lung, which was very much diminished in size, carnified, and destitute of air. The adhesions were so firm that the walls of the heart (which were thinned and the consistence almost of brown paper) gave way in one or two places while the false membranes were being broken down. The heart and lungs were removed together, and an aneurism about the size of a large apple was found pressing on the lower part of the trachea, the right bronchus (blocking up the passage effectually), and the right pulmonary artery.

Remarks.—All authors agree that hæmorrhage into the spinal cord is of very rare occurrence, whilst some (*vide* "Ziemssen's Encyclopædia") affirm that it is perhaps

never spontaneous; and although a few cases of hæmorrhage under or upon the spinal membranes have been reported in the medical journals, I have only been able to find one case of hæmorrhage into the spinal cord (the true hæmatomyélie of Ollivier) reported in any of the medical journals or transactions of pathological societies.

The second case of aneurism strongly simulated laryngitis, and the question of opening the trachea was at one time debated. There was no appearance of any inflammatory action, but the pericardium being throughout adherent to the heart, evidenced at some former time inflammation of that membrane; and the state of the lung and chest wall undoubtedly points to previous pleuritis and effusion.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Aneurism of the External Carotid, in which, after failure of the Ligature of the Common Carotid, the old Operation was performed successfully.—Abscess in the Neck, causing destruction of a large portion of the Carotid Artery, Jugular Vein, and Pneumogastric Nerve.

The ordinary meeting of this Society was held on the 26th inst., Mr. J. E. Erichsen, F.R.S., President, in the chair. Two papers dealing with the surgery of the neck were read. The first was an exhaustive account of a case of external carotid aneurism by Mr. H. Morris. In this case ligature of the common carotid was first attempted; but recurrence of pulsation and extension of the tumour compelled a final and successful operation of opening the sac, and securing the external carotid on the distal side. The other paper, which was by Mr. Savory, was one of remarkably extensive destruction of the great vessels and of the vagus nerve by an abscess.

The following is an abstract of the paper on a case of Aneurism of the External Carotid, in which, after failure of the ligature of the Common Carotid, the old Operation was performed successfully, by Mr. HENRY MORRIS, F.R.C.S. Elizabeth P—, aged forty-five, first came under care on May 20th, 1879, with an aneurism about the size of a walnut at the level of the hyoid bone, and just above the bifurcation of the right common carotid. It had been noticed eight months, and was growing. It was not the result of any injury. She complained bitterly of the pain it caused all over the right side of the head and neck, and of a distressing feeling of dryness about the throat and fauces. She could swallow nothing solid without great suffering; her voice was hoarse, and she spoke in rough whispering tones. Her sight and taste were unaffected. Digital and instrumental compression could not be borne. Diet and medicinal treatment were resorted to; but her symptoms becoming rapidly worse, on July 16th a catgut ligature was placed around the common carotid artery on a level with the omo-hyoid muscles where it crosses the cervical sheath. Four hours and a half afterwards faint pulsation returned in the aneurism, and continued more or less marked till August 12th, when the outline of the aneurism was quite lost, though some pulsation could still be felt along the line of the artery in the situation of, and for a little distance below, the seat of the aneurism. A sinus remained leading down to the part of the ligature, hard and surmounted with exuberant granulations, from which blood occasionally was discharged. At the end of September fresh swelling took place at the angle of the jaw, but there was no pulsation in it; with this exception all the old symptoms returned. On October 13th there was evidence of suppuration, so an incision was made, and a small quantity of pus was evacuated from the surrounding tissues. Relief was again obtained, but only partially and temporarily. Though the sinus over the ligature now closed, a similar one, from which blood occasionally escaped in small quantity, remained in the centre of the late incision. At the end of November pulsation was again felt, and the swelling, which had much subsided after the escape of the

pus, again increased; in fact, the aneurism had now evidently ruptured, was inflamed, and growing largely, and threatened to set up ulceration of the tense and distended skin. It was therefore treated in the following manner. The facial and superior thyroid arteries were first ligatured and then the sac was laid open, and all clots turned out. It was now seen that all the bleeding was issuing from the distal end of the sac, and could be checked by passing a tenaculum underneath it, and raising it. The incision was prolonged upwards sufficiently far to enable a silk ligature to be passed around the vessel beyond the sac, and in doing so a small artery and vein were cut, from which bleeding, easily controllable, occurred for the moment; this artery was probably the occipital. It was specially noticed that no blood had been passing into the sac from the internal carotid, yet that no clot was prolonged into it from the common carotid. The wound did well; the ligature separated on the seventeenth day. Convalescence was retarded by an attack of quinsy, which in the right tonsil ran on to suppuration; but the patient had quite recovered by the 12th of February, 1880, and still remains well. — *Remarks:* The return of the pulsation in the aneurism a few hours after the application of the ligature, the slow consolidation of the aneurism, the pulsation in the vessel on the proximal side of the sac, though not immediately above the ligature, the subsequent growth of the aneurism in spite of the complete obliteration of the common carotid, the violence of the hæmorrhage from the distal orifice of the sac at the time of the last operation, together with the absence of any bleeding from the internal carotid, prove how important a part the free anastomoses between the branches of the external carotids of the two sides of the neck, and between the branches of the external carotid and subclavian of the affected side, play in aneurism near the bifurcation of the common carotid. Moreover, it is suggested, and well-known cases and dissections are quoted to support the suggestion, that after the ligature of the common carotid no blood usually continues to reach the lower end of the internal carotid in the neck, and that therefore the anastomosing circulation within the skull is not the cause of the return of pulsation in these aneurisms, and therefore not a cause of the failure of the ligature. The practical conclusion arrived at is that, if the Hunterian ligation be employed in these cases, it would be best to supplement it by the simultaneous ligation of such branches of the external carotid as are easily accessible—viz., the temporal, facial, and superior thyroid.—The PRESIDENT remarked that the paper contained some valuable practical suggestions, to which he invited the attention of surgeons present—especially the question of the simultaneous ligation of the accessible branches of the external carotid in cases of aneurism of that artery, with a view to diminish the collateral blood-supply.—Dr. HILTON FAGGE referred to a case confirmatory of the views enunciated in the paper. It was a case of aneurism (he believed, at the origin of the external carotid) in a man who was hemiplegic on the same side. The common carotid was ligatured, and shortly after the hemiplegia disappeared. Some time after the patient died, and the cause of this singular fact was found in the position of the aneurism. It lay over the internal carotid, and probably compressed this vessel so as to diminish the supply of blood to the brain, until after ligature, when the shrinking of the sac relieved the internal carotid of this pressure. Supposing this explanation were correct, it confirmed the author's view; for if the circle of Willis had sufficed to carry on the circulation there would have been no reason for the hemiplegia occurring.—Mr. CRIPPS was not quite clear whether the diagnosis of external carotid aneurism was made before ligature was applied. If so, why was it deemed necessary to tie the common carotid below the omo-hyoid, seeing how much more dangerous that procedure was than ligature of the external carotid, the mortality after the former operation being as high as 1 to 3; after the latter, about 1 to 20 (Guyon). If the trunk of the vessel had been exposed, might not the external carotid have been secured below the aneurism? In spite of the confirmation given by this case to the collateral supply being mainly kept up through the branches of the external carotid, he did not think this could be always the case. In a paper he read before the Society two years ago he showed that in some cases the circulation was maintained by a recurrent flow in the internal carotid; and it was hardly conceivable on hydrostatic grounds that there should not be such a flow. In Mr.

Morris's case, however, when the sac was opened no bleeding occurred from the proximal end of the external carotid, and yet the clotting did not extend beyond the bifurcation of the common trunk. He thought also that the fact of the bleeding from the distal end, in spite of ligature of the facial and superior thyroid branches, rather detracted from the value of the suggestion to secure the peripheral branches in order to prevent this collateral flow of blood. He thought the supply of blood would be more effectually controlled if the external carotid of the opposite side were ligatured.—Mr. HOLMES was reminded of a case brought before that Society many years ago by Mr. P. Hewett. The surgeon—he believed Sir B. Brodie—had tied the external iliac for femoral aneurism. For a time the disease was arrested; then the tumour increased in size, and at first was so like a malignant growth that those who saw it were under much the same doubt as to its nature as Mr. Heath had been in the present case. The tumour continued to grow, and then pulsation recurred in it. Local pressure (which of course could not be applied in Mr. Morris's case) successfully prevented further extension of the aneurism. The man died subsequently from some other affection, and the preparation of the parts showing the cured aneurism and enlarged collaterals is in St. George's Hospital Museum. Referring to Mr. Cripps' criticism, Mr. Holmes said that it was clear from the extent of the tumour, which reached to a level with the hyoid bone, that it would not have been possible to have placed a ligature higher up than Mr. Morris had done. He agreed with Mr. Morris as to the additional security afforded by ligature of the main vessels which carry a collateral circulation, for although all the channels cannot be closed, yet the cutting off of several would much diminish the risk of recurrent pulsation. And in cases of aneurism of the neck the free anastomoses precluded any fear of gangrene following the ligature of these collaterals. He also concurred in what the author had said about the difficulty of diagnosing between an aneurism of the external and one of the internal carotid. The course taken by the blood in collateral circulation after ligature did not follow any hydrostatic laws, so many elements interfering—e.g., the internal carotid might be occluded by a small piece of clot.—Mr. HEATH hardly thought the plan of tying the branches of the external carotid practicable. Certainly some, as the maxillary branches, could only be secured at great risk. He would rather advocate the use of the galvanic current, or the injection of perchloride of iron, into the sac, to hasten coagulation, in addition to the ligature of the main trunk. He could not see how tying the opposite external carotid, as suggested by Mr. Cripps, would have much influence.—Mr. HULKE said that injection of the perchloride of iron was attended with great risk, unless the passage of blood was completely controlled. Many years ago, in some experiments upon the effects of such injection into the blood-stream, he had found that after injecting the fluid into the large vein that crosses the tendo Achillis in the dog clotting passed almost instantaneously into the main veins, and even into the heart, if the circulation were not arrested in the vein. But when the circulation was controlled on either side of the seat of injection, the coagulation was limited to that spot.—Mr. MORRIS, in reply, was surprised that an anatomist and surgeon of Mr. Heath's experience should have thought it a difficult matter to secure the superficial branches of the external carotid. Of course the deep branches would not be tied, but the occlusion of the accessible vessels would so far diminish the blood-supply as to put the aneurism in a more favourable condition for cure. It was not that coagulation did not take place in the sac—for there was abundant coagulum—but the free collateral supply allowed the clot to rest, and prevented it from consolidating. The description of many of these cases leaves the reader in doubt as to whether the blood-flow does enter the external carotid from below by a recurrent flow in the internal carotid, or whether the current is down through the external carotid and up into the internal. Certainly in this case it seemed to have taken the latter direction, and also in Hobson's case. The conditions of circulation with regard to the two carotids differed from those obtaining in other parts of the body, for there were large vessels bringing in blood from anastomosis on the same side, as well as possibly (sometimes) from the internal carotid. The recurrent pulsation was probably due to each additional influx of blood from these sources, and not to the direct influence of the heart. A similar explanation might be given of recurrent pulsation when both femoral artery and vein were tied, as in Porter's case. It was impossible to

tie the external carotid from the position of the aneurism. He referred to an essay recently published in the Transactions of an American Society, where the surgery of the carotid arteries were exhaustively dealt with.

The next paper, on a Case of Abscess in the Neck, which in its course destroyed a large portion of the carotid artery, jugular vein, and pneumogastric nerve, was contributed by Mr. WM. S. SAVORY, F.R.S. In this paper, after a short account of two instances, in one of which the internal jugular vein, and in the other the femoral artery and vein were laid open by an abscess, a case is related of a man who was brought to the hospital in a state of extreme prostration, the result of hæmorrhage, from a large orifice of an abscess at the left side of the neck, which had given way three days previously. He never fairly rallied, and died on the fourth day from his admission. On dissection the cavity of a large abscess was exposed, in the upper and lower parts of which portions of the carotid artery, jugular vein, and pneumogastric nerve were found. But a considerable piece of each was wanting. The opposite ends of the divided artery were from one and a half to two inches apart; the distance between the ends of the vein was rather more than this; the ends of the nerve were from one to one and a half inches apart.—Dr. J. HARLEY said that he had once excised about an inch and a half of one vagus nerve in a young dog, and no physiological effects whatever followed.—Dr. DOUGLAS POWELL asked whether the author could offer some explanation as to the reason why those vessels and nerves had been so widely destroyed by the abscess. Such an event must be very rare. Was it due to the pressure of the abscess or the cutting off of the blood-supply to the walls of the vessels?—Mr. SAVORY, in reply, said he could offer no further explanation than that the vessels were destroyed by the very intensity of the inflammatory process; for although it was well known that, from their peculiar structure, bloodvessels resist such destruction more than other tissues, yet he supposed their escape was only a question of the degree of inflammation.

The Society then adjourned.

CLINICAL SOCIETY OF LONDON.

Cross-legged Progression, owing to Double Hip Anchylosis.—Acute Intestinal Obstruction by Hernia, through Mesentery of a Meckel's Diverticulum.—Nephro-lithotomy.

THE ordinary meeting of this Society was held on the 22nd instant, Dr. E. H. Greenhow, F.R.S., President, in the chair. The communications read were of a highly interesting character. Mr. Clement Lucas drew attention to a curious mode of progression in two subjects of old disease of both hips, where the legs were crossed over one another. The patients were exhibited. A rare example of Acute Intestinal Obstruction was communicated by the President. Mr. Henry Morris related a case of Renal Calculus, which had been extracted by operation before the stone had excited destructive disease of the organ. Mr. Morris proposed to term this operation nephro-lithotomy; and the advisability of such interference in similar cases was generally admitted. The patient in this case also was shown to the Society.

Mr. CLEMENT LUCAS read a paper on "Cross-legged Progression (scissor-legged deformity), the result of Double Hip Anchylosis." The object of the paper was to direct attention to a peculiar and characteristic gait brought about by anchylosis of both hip-joints, and hitherto undescribed. Two patients were exhibited to illustrate the cross-legged mode of walking—one a boy, aged ten, and the other a man, aged forty-seven. In each case the disease had existed some time in one hip-joint before the other had become affected. Gradually, as the patient walked with the aid of sticks or crutches, the limb last attacked was carried across the other, and becoming ankylosed in this position compelled the patient to walk permanently cross-legged. The legs, placed in this position, suggest in their crossing the appearance of a pair of scissors. The author left it open to discussion how this position was acquired—whether as the simple result of the adduction which is so common a sequence of hip disease, or as the gradually developed, perhaps unconscious, action

on the part of the patient to place his limbs in the position most favourable for progression. Mr. Lucas gave the following explanation as the most probable: The patient, when commencing to walk on the convalescent limb, finds that by resting the other limb upon it, he can steady the inflamed hip and prevent the movements which caused him pain. At the same time by the oblique position the limb is shortened and rendered less liable to touch the ground. As recovery goes on in the hip last attacked, the patient from time to time tests its condition by dropping the supported foot on the ground and bearing a little weight upon it. Gradually he takes more and more weight from the crutches, still retaining the limb in the oblique position, and finally, the second hip having become ankylosed, he is able to throw aside his crutches and walk in the peculiar manner illustrated by these two patients. The author showed that in ordinary walking the forward movement takes place entirely from the hip, the knee movement being of service only to shorten the limb and prevent the foot touching the ground when in the act of being advanced. Hence, should both hips become fixed when the limbs are parallel, progression could only take place by twisting first one side of the body, then the other, to the front. The patient finds out for himself that by carrying one limb across the other, so as to render the knees oblique, the knee movement can be made to take the place of the hip movement, and knee-walking is thus substituted for hip-walking. In both the patients exhibited, the right leg—that last attacked—was in advance of the other. The first patient, a boy, aged ten, began to suffer from disease of the left hip when four and a half years of age, and attended as an out-patient at the Evelina Hospital. Fifteen months later, after a fall, the right hip became diseased. He continued under Mr. Lucas's care till June, 1877, when he was admitted into the hospital under the care of Mr. Morratt Baker. After resting in the hospital three months he was discharged, and again attended as an out-patient. For twelve months after his discharge he was kept lying during the greater part of the time; he was then allowed to walk with crutches, the left hip having become ankylosed. He was then sent into the country, and on his return it was found that he had learnt to walk with both legs, but that they were fixed in the scissors-like position. The second patient exhibited Mr. Lucas saw walking in the street, and diagnosed his condition by the light of the other case. This man, aged forty-seven, first began to suffer pain in the left hip in 1870. He was at the time employed as a coal-heaver. He sought advice at St. Thomas's Hospital, and afterwards at St. Bartholomew's. Subsequently he spent thirteen months in the Dalston Infirmary. After this, for a year he tried to work a little, but remained lame. Since that time he has gained his living by selling trifles in the street. In September, 1877, he began to suffer pain in the right hip. Up to this time it had been his custom to rest the greater part of his weight on this limb, but the pain now caused him to stand chiefly on the left leg. In the course of the winter he got into the habit of crossing his legs, but at first was able to unlock them at will. Later, he used to unlock them at night-time when he retired to rest, but gradually this became more difficult, and they are now firmly fixed in the cross-legged or scissors-like position.—Mr. CROFT said that amongst the cases of hip disease brought by him to the Society last session there was one of double ankylosis in a girl, but her condition was slightly different from those brought forward by Mr. Lucas, for in her case there was not so much displacement as in these. She walked with the right knee in advance of the left, and managed to bring one foot in front of the other in progression. There was much lordosis. Her progression was much improved by division of the left femur, below the great trochanter, and forcible breaking down of the adhesions on the right side. He did not think then that the curious condition shown by Mr. Lucas was a necessary outcome of double hip disease. In the child there was dislocation on both sides, with eversion and extreme adduction. It appeared from his history that the disease began on the left side first, and that the limb was flexed and adducted when he left the hospital, and he was obliged to cross the legs to maintain the centre of gravity between the two heels. It was very interesting that there should have been so much destruction of the head of the femur on each side as to lead to this displacement without any abscess. The other case might perhaps be similarly influenced, but he had not examined it. He would suggest that the femur should be

divided below the trochanter in the boy's case, first on the one side, then on the other, and the limbs brought parallel, for in his present state he would be debarred from ever obtaining active employment. That double hip disease does not incapacitate a man from active duties, he instanced the case of a village postman, the subject of this affection, who walks from the pelvis and knees.—Mr. HOWARD MARSH confirmed Mr. Croft's supposition as to the mode in which this condition had been brought about, and thought it showed the importance of trying to cure double hip disease without allowing adduction to take place. He believed the peculiar gait was due to the fact that the limbs were allowed to get well into a state of adduction, and they were extended on the trunk. In cases of congenital dislocation of the hip the knees are flexed when walking. In Mr. Lucas's cases there did not appear to be this flexion, and in order to maintain the centre of gravity they were obliged to cross their legs. He was in the habit of preventing the tendency to adduction in cases of unilateral disease by placing a splint on the outer side of the limb, to keep it straight, and a small splint from the knee to the outer side of foot, with a weight suspended to it. He did not think the peculiar gait was simply due to the double hip disease, for he had seen cases which walked like that one last mentioned by Mr. Croft. He concurred in Mr. Croft's suggestion as to the advisability of performing osteotomy in the boy's case.—Mr. LUCAS, in reply, said that he was obliged to Mr. Croft for showing how the peculiar position of the limbs in these cases was probably due to ankylosis in adduction. It was interesting that this position should be acquired, especially if they became ankylosed thus. Were the limbs almost parallel it would be impossible for any stride to be made without flexion of the knees; and Mr. Croft's case showed that even the knees tend to become adducted. The cross-legged position allows of the knee acting as a hip to a certain extent, and also permits the knee to have a certain forward movement. The only operative measure would be to divide the femur below the trochanter, or at the site of the original neck; but it was doubtful if much improvement would ensue, for the boy already can run at a great pace, and takes part in cricket and other outdoor games. If the femora were to be divided, and the limbs straightened, his activity would be reduced. If he operated, he would first divide one femur, and would try to prevent ankylosis. In reply to Mr. Heath, he said that he did not think the heads of the femora were dislocated in the man's case.—Mr. HEATH thought they were not dislocated in that case, and that being so, it was curious that the cross-legged position should be the same in the two cases.—The PRESIDENT nominated Messrs. Heath, Croft, and Lucas to examine the cases upon the question of dislocation, and to report to the Society.

The Secretary read a paper, contributed by the PRESIDENT, upon a case of Intestinal Obstruction caused by a Hernia through the Mesentery of a Meckel's Diverticulum, which had retained its attachment to the umbilicus. The patient was a boy, seven years of age, who was seized with severe pain in the abdomen in the evening of May 31st, 1880. The pain was referred to the umbilicus, and was relieved by the sitting posture. He had occasionally suffered from attacks of pain previously, but the bowels had been opened freely the day before the fatal seizure. Examination of the belly yielding negative results, a poultice containing laudanum was applied, and small doses of opium were given by the mouth. Vomiting set in on June 2nd, and recurred with varying severity several times in the course of the illness. The urine was scanty and of high specific gravity. Paroxysms of pain continued at intervals, and enemata administered daily brought away fecal masses almost to the last. The pain was less on the 4th and 5th, but it recurred severely on the 6th, with increased distension of the belly, and the child rather rapidly sank in the evening of this day. The vomiting was never fecal. The treatment consisted in sedative applications and the internal administration of opium and belladonna, as well as enemata. The post-mortem examination, by Dr. Coupland revealed commencing peritonitis, and about two feet of the lower part of the ileum were found hanging in a collapsed condition on each side of a cord-like loop. This loop was formed in the mesentery of a well-developed diverticulum, the upper end of which was attached to the umbilicus by an impervious cord half an inch long, the diverticulum itself being four inches in length. The gut, where it passed through the loop, was constricted and pale, but a small projecting portion at the origin of the diverticulum was of a deep purple colour.

Above the constriction the bowel was distended with fluid faecal matter; beyond it was empty. Dr. Greenhow remarked that he had been unable to find on record an exactly similar case to the above. When he first saw the case he was led to exclude intussusception and inflammation of the appendix caeci; nor did evidence of peritonitis supervene until the day before death. Complete obstruction did not take place until twenty-four hours before death, although the ileal coils might have been partially included in the loop for some time. The great relief obtained in the sitting posture was probably due to the fact that in that position the viscera were thrown forward towards the abdominal parietes. Abdominal section was entertained, but dismissed in the early days of the illness; and collapse supervened too rapidly upon the serious symptoms for operative interference. Even had this been attempted it is likely that the diverticular attachment would alone have been recognised and divided, the existence of the loop not being suspected.—Dr. COUPLAND explained that the constricting cord was probably formed by the relics of the omphalo-mesenteric vessels which accompany the vitelline duct to the umbilical vesicle, and which, if persistent, would naturally occupy the fore margin of the triangular fold of peritoneum forming the mesentery of the diverticulum. The ring was formed by this cord becoming detached from the diverticular mesentery. The cord passed on to the surface of the true mesentery just beyond the origin of the diverticulum.—Dr. SILVER asked the President as to two points suggested by the case—viz., as to the advisability of abdominal section, and as to puncture of the distended bowels. Although ovariotomy had taught that the peritoneal cavity might, with due precaution, be opened with impunity, at what period of a case is it advisable or safe to urge the procedure, supposing peritonitis were present? As to puncture of distended coils to allow of escape of gas, he had known this afford great relief and ward off impending death; but in these cases no peritonitis was present.—Dr. GREENHOW, in reply, did not think that in this case any operation was advisable, or that the constricting band would have been detected. No hard and fast line could be laid down as to the propriety of operating. The great relief afforded by enemata and the absence of peritonitis seemed to show that in this case obstruction was not complete until near the close. Nor was there any distension calling for puncture until within sixteen hours of death, and the question of puncture did not arise. He should hesitate, too, about advising puncture, especially in the presence of peritonitis.

A paper was then read by Mr. HENRY MORRIS upon Nephro-lithotomy, with a case in which the operation was successful. By the term "nephro-lithotomy" is meant the removal through a lumbar incision of a renal calculus from a kidney in which the pelvis is not dilated; and which, but for the presence of the stone, is presumably healthy. It is to be distinguished from the numerous cases in which the kidney is cut for the evacuation of fluid accumulated within it, whether as the result of a renal calculus, of tubercular disease, or some other cause, and to which from very ancient times the name "nephro-lithotomy" has been applied; as well as from those cases, also numerous, in which a stone has been removed after it has been detected through a sinus in the loin. The opinion of writers on the subject has been universally adverse to the attempt to remove a stone from the kidney unless it could be reached through a distended pelvis; the chief reason urged being the danger of fatal hæmorrhage if the excreting substance of the organ was cut or torn. The case described in the paper conclusively proves the feasibility of the operation, and in answer to the question, Is nephro-lithotomy feasible? and if feasible, is it safe? the author stated "that it is entirely due to his friend and colleague, Dr. Coupland, who advised the patient to undergo the operation, that an affirmative answer can now for the first time in the history of surgery be given with certainty to this question." The position of the question before this case occurred was reviewed; Marchetti's operation on the English consul, Hobson, was referred to; and six cases in which the operation was planned, but in which it proved abortive, were mentioned. These six cases were considered encouraging because all the patients recovered from the operation of exposing the kidney; and curiously enough obtained, at least for a time, relief from their symptoms.—*Case:* Maria M—, aged nineteen, a servant-girl of short stout stature, and with a remarkably rough scaly skin, had for eight years been subject at times to pain in her right side, accompanied occasionally with a feeling of sickness,

and even actual vomiting. In September, 1878, these symptoms became more pronounced; her urine became dark-coloured, and the pains so severe that she had to give up her situation and go under medical treatment. In April, 1879, she was admitted under Dr. Thompson into the Middlesex Hospital, and after treatment and rest so far improved that she went again into service. A life of activity, however, brought back the old symptoms, and she was readmitted into the hospital, this time under Dr. Greenhow. In less than a month she was again able to go out, but only to return a third time, with urine as dark as porter, and with the pains in the right loin and groin as severe as ever. When she was admitted under Dr. Coupland on Dec. 29th, 1879, her urine was acid, and contained no other abnormal constituents than blood; there was some tenderness, but no swelling, in the right loin. Again the urine cleared up, but the nephralgia was not relieved; consequently, on Feb. 11th, chloroform was administered and the right kidney exposed through an oblique lumbar incision. The right index-finger was then passed over the posterior surface of the kidney, and at once detected something faintly projecting from the renal substance near the hilus. The renal substance was incised at the spot with a probe-ended bistoury, and a mulberry calculus of triangular shape, weighing thirty-one grains, was extracted by means of a scooping movement of the finger-tip. There was no hæmorrhage at any stage of the operation. The upper end of the ureter was not dilated in the least, nor could the stone be felt there; it was consequently not interfered with. No attempt was made to examine the front surface of the kidney. The wound was brought together with three sutures, and a drainage-tube introduced between two of them. The patient made a good recovery. Urine ceased to flow through the wound on May 4th, and at the present time there is nothing whatever the matter with the patient excepting that a sinus of an inch and three-quarters still remains in the loin, and discharges about a drachm of pus daily. Thus the case shows that a calculus may be extracted from an undilated kidney by surgical operation without more risk than is amply warranted by the sufferings and general disability which the operation was designed to remove. But before the success of one case is allowed to influence treatment in others four questions require consideration. 1st. Can the diagnosis as to the disease, and the organ affected, be made with certainty? 2nd. What are the prospects of being able to complete the operation when a stone is found? 3rd. What are the dangers of the operation? 4th. What is the best result which can be hoped for from the operation, if successful? Mr. Morris gave arguments in answer to each of these questions in favour of nephro-lithotomy, and, finally, expressed his agreement with Mr. Charles Bernard, the author of an account of Marchetti's operation in the Philosophical Transactions of 1696, that many of the writers upon the subject of wounds of the kidney "ought not to have so magisterially exploded the operation," and hoped the operation would once again receive the consideration of the profession.—Mr. CLEMENT LUCAS had not the slightest doubt that nephro-lithotomy was both justifiable and practicable; and he had been for some time on the look out for a case which would call for such an operation. The successful results of nephrectomy supported the undertaking of other operations on the kidney. The lumbar incision is trifling, and the incision of the kidney itself is not dangerous. But it would be a serious objection if in every case a permanent urinary fistula was left; and he asked Mr. Morris if means might not have been taken to avoid this (e.g., by keeping the patient in the prone position), and whether he contemplated doing anything to relieve it?—Mr. MORRIS explained that no urine had passed through the sinus for a long time. It was now but a short sinus, discharging only a few drops of pus.—Mr. LUCAS said that his criticism then fell to the ground. He had the notes of a case of sinus in the loin, due to renal calculi which he had removed from the kidney, but on the suggestion of the President he did not relate the case, as the President pointed out the question before the Society was that of operation for the extraction of renal calculus without previous suppuration.—Mr. GOLDING BIRD congratulated Mr. Morris on the result of his case, and wished to add a seventh to the six he had mentioned where no stone was found. He had referred to this case at the Society last session. The patient was a lad, admitted into Guy's Hospital last autumn with an impacted calculus in the urethra. This was removed, but he began to suffer from intense renal neuralgia

on the left side, and from pain in the bladder, so that his life was rendered intolerable. Mr. Bird, thinking these symptoms pointed to stone in the left kidney, and the lad's misery being so great, he cut down on the organ, thoroughly explored it, back and front, but found nothing beyond a small nodule at one part the size of a millet-seed. He did not incise the kidney, but closed the wound. There was temporary relief, but then the pains returned; and Mr. Durham cut into the bladder, again without finding a calculus, but again with relief from the neuralgia for a time. Mr. Golding Bird did not know what had since become of the patient.—Mr. BARKER mentioned a case published in the *Berliner Medic.-Wochenschrift* a few weeks ago by Peters. There were symptoms of renal calculus, which the author verified by passing a trocar and cannula into the kidney, and striking a stone. Unwilling to subject the patient to the risks involved by cutting down on to the kidney, he left the cannula *in situ* for some time, and afterwards dilated the wound by tents until the sinus was large enough to admit the finger. He then passed in a lithotrite and crushed the stone before removing it. The fistula healed up completely. Within the last month Mr. Barker had himself operated on a case of renal calculus, which, however, proved fatal. The organ was readily exposed and incised, but the calculus was found to be of large size and branched. He removed part of it, and some pus escaped. Unfortunately a large portion of the calculus remained behind, and its extraction being difficult he was led to attempt the removal of the whole organ. But unable to enucleate it perfectly he found, after all, that it was easier to remove the calculus, which he accordingly did. Another point was the possibility of diagnosing a stone in the kidney. He saw the patient last February, and then made the diagnosis, which rested between renal calculus and tubercular disease. By passing a needle through the loin he struck the stone; and he believed this was the first time in which a renal calculus had thus been sounded *through the loin*.—Mr. BRYANT wished to support Mr. Morris as to the advisability of performing the operation. For as the operation was not one of great difficulty, it was not always of great simplicity, and should not be undertaken without grave consideration. Granting the diagnosis of stone in the kidney, and the want of relief in spite of medical skill, then there would be but little hesitation in the surgeon cutting down to remove the calculus. But all knew of cases where a calculus settles down, and the patient lives for several years no longer troubled by it; such cases might make one hesitate in arguing in favour of operation. The method of diagnosis alluded to by Mr. Barker was interesting from the fact that a stone in the kidney could be struck through a puncture in the loin, but he should doubt the expediency of such attempts in view of the important structures in the neighbourhood which might be injured. To clear up a doubt it might, however, be expedient to use these means. The procedure, however, was not quite analogous to the puncture of the intestine. He was pleased to hear such a case, and congratulated the physician and surgeon upon it.—Dr. GLOVER asked whether the occurrence of desquamation of the skin was coincident with the administration of turpentine? He had recently had a case of renal calculus under his care, in which the taking of this drug was followed by considerable desquamation, almost like that following scarlet fever.—Mr. HEATH, without wishing at all to detract from the value of the operation, ventured to remark that it was done under unusually favourable circumstances. The patient was young and the stone presented on the surface, so as to be readily identified. As it protruded the renal substance, there was not much of the organ incised. Mr. Barker opened the kidney in his case by means of Paquelin's cautery. He thought a puncture might be made in the loin for the diagnosis of calculus without any risk: it only required a fine aspirating needle, and the large vessels were far out of danger. In the case of a small calculus—as in Mr. Morris's case—it would be very fortunate if detection could be effected in this way.—Mr. MORRIS, in reply to Mr. Lucas, said that surgeons had always recognised the propriety of removing calculi when a sinus existed. He was glad to hear of Mr. Golding Bird's case, which added another to the list of those where the kidney had been cut down upon without a stone being found. Mr. Annandale, in a letter to him, said that he had operated on a gentleman and fairly handled the kidney without feeling a stone; but the operation was followed by recovery from the symptoms of calculus. So that these

cases would seem to imply that great relief might be obtained by the mere incision in cases of renal neuralgia. Mr. Annandale suggests that the incision acts as a counter-irritant. He had not read the case referred to by Mr. Barker, as recently published abroad. In Mr. Barker's own case was the pelvis distended or not? Was there much pus let out? If so it did not fall under the category of cases of nephro-lithotomy proper. Dawson had detected a stone by puncture through the loin. If acupuncture were used, it would be far more certain of success if applied to the kidney itself. He agreed with Mr. Bryant as to the dangers involved in this procedure. In reply to Dr. Glover, he said that the condition of skin was of long standing in this case, and it improved very much after the removal of the calculus. He concurred with Mr. Heath in the case being a most lucky one, from the small size of the stone and its projecting into kidney substance. But there was considerable incision and laceration of the kidney in the extraction of the stone.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Paralysis of Lower Limbs following Pelvic Abscess, on profuse loss of blood after Abortion.

At the meeting of this Society on the 25th inst., Mr. F. J. Gant, President, in the Chair, a paper was read by Mr. WM. ADAMS, entitled "Cases of Paralysis with Contraction of One Leg, following pelvic abscess in women; and of both legs following excessive loss of blood after miscarriage." The pathology of these two forms of paralysis with contraction in women is very different; one referring to damage done to the nerve trunks of the sacral plexus by inflammatory exudations, from which only imperfect recovery is likely to occur, and the other to some obscure affection of the spinal cord itself, probably involving slight structural change in the motor tract, from which a good, though not quite complete recovery may occur. In the *first class* the accumulation of pus in a pelvic abscess, instead of advancing, as it generally does, along the iliac region, and opening through the abdominal parietes, passes backwards and upwards, opening through the rectum or vagina. The nerve trunks of the sacral plexus become imbedded in lymph, which in time contracts, and, so to speak, strangles the nerves, leading to paralysis, with loss of sensation and motion, more or less complete on the affected side, from the hip downwards. The recovery from this condition in the case brought forward has been very imperfect. After a period of four years, the limb only being rendered useful in walking by mechanical support. In the *second class* the pathology is more obscure. In the case adduced, partial paralysis with contraction of both legs occurred within three weeks of a miscarriage, followed by excessive loss of blood, from which there seemed to be but little hope of the patient recovering. This condition was by some supposed to be the result of "myelitis from loss of blood"; by others, "spinal anæmia." Another suggested explanation was that it depended upon a purely functional derangement. Opposed to the last suggestion, Mr. Adams considered were two important objective symptoms: first, the muscular wasting and general atrophy of the legs; and, second, the peculiar atrophic condition of the skin, which was thin, white, and shiny; predisposed to tear on slight stretching, and corresponding to the so-called "glossy skin" described by Weir Mitchell, Charcot, and Paget as amongst the changes in nutrition of tissues resulting from nerve lesions. The conclusion, therefore, Mr. Adams arrived at was that structural changes had occurred in the motor tract of the spinal cord, from which considerable, though not complete, recovery has taken place up to the present time—six and a quarter years since the miscarriage. The muscles of the hip-joint, and some muscles of the legs, still remain partially paralysed, but she is able to walk with some assistance. The surgical treatment in the late stage of contraction consists in tenotomy and gradual mechanical extension, either by the use of instruments, or weight and pulley. Forceful extension should never be employed to overcome muscular contraction. With a view of promoting the recovery from the paralysis, Mr. Adams recommended galvanism, shampooing, passive motion, and warm clothing.—The PRESIDENT alluded to

the suggestions raised by the author as to the nerve pathology of these cases. He also pointed out the advantage of tenotomy, especially when combined with extension, in overcoming contractions.—Dr. ALLEN STURGE, who had examined the second patient referred to by Mr. Adams, stated that in the right leg there was very marked weakness of the flexor muscle of the thigh and of the muscles of the calf, complete paralysis of the tibialis anticus and extensor proprius pollicis, the extensors of the thigh and the peronei being nearly or quite healthy. In the left leg there was marked weakness of the psoas and iliacus, of the flexors of the thigh and of the calf muscles, the extensors of the thigh and the muscles in the front of the leg being healthy. The paralysed muscles were almost completely wasted, and their reaction to faradism was greatly diminished. The condition then was paralysis of groups of muscles in the two legs, with wasting and loss of electrical reaction, without loss of sensation or affection of the bladder—the exact condition seen in infantile paralysis. Dr. Sturge believed, therefore, that the lesion was the same as in the latter disease—viz., acute inflammation of the anterior horns of grey matter in the spinal cord. This condition is now well recognised as occurring in adults, and recently it has been met with as a sequel to typhoid fever and small-pox. May it not therefore occur after parturition or other acute exhausting disease?—Dr. ALTHAUS said that the paralysis in the first case was clearly owing to neuritis of the sacral plexus, the inflammation spreading from the pelvic cellular tissue to the nerves. The second case was more obscure, and he discussed the various probable conditions. He discarded the possibility of functional derangement without structural disease. Spinal anæmia occurred after hæmorrhage, not only from the womb, but also from the bowels or kidneys, after profuse epistaxis, and occasionally in chloro-anæmia, leading to paraplegia; but it was invariably recovered from under appropriate treatment. Ischæmia of the cord, due to embolism or thrombosis, was clearly not present in this case. There only remained meningo-myelitis, and, looking to the early rigidity, he thought that it probably was a case of pachymeningitis with compression of the cord by inflammatory products, especially of the lateral column.—Dr. ROUTH thought cases of pelvic cellular abscess passing into paraplegia must be rare. He had not met with one in his own practice, and he thought this might be due to his habit of opening these abscesses very early. He related a case he had seen in consultation, where paralysis with contraction followed a pelvic cellulitis; and vaginal examination under chloroform revealed a fibrous mass attached to the sacrum. The copious hæmorrhage in Mr. Adams' second case may have been due to a fibroid growth.—Dr. EDIS mentioned a somewhat similar case, where a lady, having fallen in the street, being four months pregnant, suffered from hæmorrhage, retroflexion, and septicæmia. The latter gave rise to much anxiety, although there was no evidence of local pyæmic deposit. Within six weeks from the accident paraplegia, with contraction of the legs and thighs, occurred. This was treated by forcible extension under chloroform and by mechanical appliances, with considerable benefit.—Dr. HERMAN advocated early aspiration of pelvic abscesses. He related a case recently under his care at the London Hospital where paralysis had followed pelvic mischief.—Dr. HEYWOOD SMITH asked for information as to the relative rate of absorption in abscesses opened by puncture and those allowed to open spontaneously.—Dr. DOWSE thought the symptoms of the second case pointed to meningo-myelitis.—Dr. HORROCKS believed the pathology of that case was similar to that found in infantile paralysis. The inflammation wholly destroying some motor nerve-cells and irritating others was sufficient explanation of the paralysis of some muscles and the contraction of others.—Mr. ADAMS replied, and the Society adjourned.

MIDLAND MEDICAL SOCIETY.

THE inaugural meeting for the session 1880-81 was held on Wednesday night, October 20th, at the Grand Hotel, Birmingham, Dr. Savage (President) in the chair. About 170 members and friends were present, including Drs. Thorburn (Manchester), T. and E. Underhill (Tipton), Parkes, Crabbe, Kely, George J. Lloyd, Melson, Warden; M'Munn, Millington, and Totherick (Wolverhampton); Wade, Malins, Sawyer, Lyle, Rickard, Clibborn, Hickinbotham,

Drummond, Thomas, Carter, Hinds, Vinrace, White, Bassett, O. Shaw, Hyde (Worcester), Messrs. Berry, West, Lowe, Hartill, Holbeche, Hollinshead, Gamgee, B. May, Chesshire, Lloyd Owen; Newnham and Lycett (Wolverhampton), Rhodes, Mann, T. W. Williams, Duncalfe, Yates, G. Elkington, E. A. Elkington (Newport), F. Jordan, Priestley Smith, Palmer, Clavasse, Archer, Lawson Tait, Bates, Harmar (treasurer), Garner and Eales (secretaries); Professors Poynting and Bridge, and Messrs. Adams and Ady (Mason College).

Dr. Matthews Duncan delivered the address, taking for his subject the treatment of puerperal fever (published in another part of our impression). At the close of the address a hearty vote of thanks was proposed by Mr. Berry, seconded by Dr. Bassett, and carried by acclamation. About sixty remained to entertain Dr. Duncan at supper. After the usual loyal toast his health was proposed by the President. Dr. Duncan in reply, proposed "Success to the Midland Medical Society." Mr. Lawson Tait proposed "The Visitors," to which Professors Poynting and Bridge replied. Mr. W. Thomas (ex-president) proposed "The Health of the Officers." Mr. Harmar (treasurer) and the secretaries having replied, the meeting separated after a very enjoyable evening. Before the address Professor Poynting showed some interesting physical experiments, including electrified water-jets and the phonendoscope. Messrs. Salt and Son and Mr. W. G. Mappin exhibited surgical instruments and appliances; Messrs. Southall Brothers and Barclay exhibited new and rare drugs and Mr. Gamgee's absorbent pads, and Mr. Bailey a collection of microscopes with beautifully prepared objects.

Reviews and Notices of Books.

A Text-book of the Physiological Chemistry of the Animal Body, including an account of the chemical changes occurring in disease. By ARTHUR GAMGEE, M.D., F.R.S., Professor in the Victoria University, Manchester. Vol. I. London: Macmillan & Co. 1880.

WRITING more than two hundred years ago, the Hon. Robert Boyle remarked that unless a physician was so instructed as to "know how heat and cold, fluidity and compactness, fermentation and putrefaction, viscosity, coagulation, dissolution, and such-like qualities, are generated and destroyed in the generality of bodies, he would often have very much to seek when he had to investigate the causes of preternatural accidents in men's bodies, whereof a great many depend on the presence, or change, or vanishing of some or other of the enumerated qualities in some of the fluids and solid substances that constitute the body." Since that passage was written the progress of pathological research has continued uninterrupted, and in the direction of histology the work accomplished must be considered eminently satisfactory. But when we come to ask what are the antecedent conditions which bring about the structural changes observed under the microscope, we find ourselves still on the threshold of inquiry, and we seem to pass at once from the domain of fact to the region of hypothesis. As yet we know little, if anything, of the variations that daily and hourly occur in the chemical composition of the blood, and which must have an important influence on the changes taking place in the tissues of the body. We have also yet to learn what mutual and separate action—physical as well as chemical—the constituents of every cell has on its growth and maintenance, and how far excess or diminution of one or more of these constituents—albumen, the hydrocarbons, salts, and water—influences oxidation and nutrition going on in the textures. The importance, however, of chemical research in this direction as an aid to pathological progress receives fuller recognition every day. Few hospitals are now without physiological and chemical laboratories in which students can obtain the manipulative skill as well as the theoretical knowledge which they require for practical work, and as the number of skilful workers becomes greater, so most certainly

will our knowledge develop with it, and become more extensive, more accurate, and, above all, more practical.

In the volume before us the author has considered the subject of physiological chemistry from a point of view which will recommend it rather to the biologist and the physician than to the chemist—that is to say, he has adopted a classification of the subject based entirely on morphological considerations. Nevertheless, care has evidently been taken that no chemical fact should be omitted which appears likely to throw light upon biological questions. The book is written in the interest of the truly scientific student anxious not merely to learn what has already been ascertained, but also to engage in original research for himself. In the present volume the chemical composition and the chemical processes relating to the elementary tissues of the body are treated of, the blood-lymph and chyle being also included. A second volume, however, is promised, in which the chemistry of the chief animal functions will be discussed.

The arrangement and plan of the whole work are excellent, and the student has here for the first time a book in the English language which is available for the study as well as the laboratory, the purely literary part serving as an introduction and reference to the student when engaged in working at the processes detailed in the practical portion of the volume. Professor Gamgee fears, however, that some may be disposed to think that he may have introduced too full a reference to the sciences of anatomy, physiology, and practical medicine; but we are inclined to regard these references, whilst adding greatly to the interest, as increasing the value of the work. Indeed, to the practical physician, the chapter which considers the changes the blood undergoes in disease is full of useful information and suggestion; the only fault is that it is too short, and, having read it, we crave for more information, and only regret that a field so rich has hitherto been comparatively neglected and yielded so little. Throughout this portion of the work Professor Gamgee has been careful to eliminate all crude chemical theories of disease, and has confined himself to the domain of experimental research, keeping before him the motto *Chymia egregia ancilla medicine, non alia peior domina*. Professor Gamgee's summary of the facts concerning the condition of the blood in diabetes, especially with reference to the production of diabetic coma from poisoning by acetone—*acetonæmia*,—is extremely interesting. As the author remarks, there are serious objections to accepting the acetonæmic theory of diabetic coma, since diabetics often evolve a most marked odour of acetone without exhibiting any tendency to develop this condition, and, further, since large doses of acetone are required to produce symptoms of poisoning, and even then these are by no means identical with those of diabetic coma. There is also a difficulty in accepting the view that the "peculiar terminal dyspnoea and coma of diabetes are due to lipæmia and fat embolism rather than acetonæmia," seeing that cases have been recorded in which, though the blood was lipæmic to a considerable degree, a most minute search at the hands of a skilled investigator failed to determine the presence of fat emboli; moreover the symptoms may occur when there is no excess of fat in the blood and no emboli are to be detected in the lungs, brain, or kidneys. In the present state of the question it is perhaps better to hold with Quincke, that the coma "is a condition which, like uræmia, is probably induced by a combination of circumstances, and by the toxic action of more than one product of tissue metabolism, amongst which may be the body which is excreted in the urine and is coloured red by perchloride of iron."

Space will not permit us to enlarge further upon the many interesting subjects treated of in this exhaustive and useful contribution to English science and medicine. Pro-

fessor Gamgee has produced a work which, when the second volume is issued, will be emphatically the text-book for the advanced student, and will be invaluable as a work of reference to the scientific physician.

Diseases and Injuries of the Eye. By GEORGE LAWSON, F.R.C.S., Surgeon to the Royal London Ophthalmic Hospital, Moorfields, and Surgeon to the Middlesex Hospital, &c. Fourth Edition. London: Henry Renshaw. 1880.

WE have on three previous occasions been able to recommend Mr. Lawson's work as the best of its kind in our language. Its good name will not suffer by the new edition. The work has been carefully and thoroughly revised. There is scarcely a page that does not show marks of improvement and revision, and here and there whole pages have been rewritten. As proof of the conscientious manner in which Mr. Lawson has done his work we may mention the following new articles: Pemphigus Conjunctivæ, p. 23; Sclerotomy, p. 79; Sarcoma of the Cornea and Sclerotic, p. 80; Mydriatics, p. 93; Myotics, p. 96; Prolapse of Iris (completely rewritten), p. 104; Cataract Operations (partly rewritten), p. 144; Nephritic Retinitis in Pregnancy, p. 172; Colour Blindness (completely rewritten, and illustrated by an excellent coloured plate), p. 220; Lacrymal Obstruction (rewritten, with drawings of modern probes), p. 290. Important additions have also been made to the articles on Foreign Bodies in the Orbit, p. 349, and on Herpes Frontalis, p. 343. In the next edition Mr. Lawson might extend the chapter on Glaucoma, especially as respects the pathology, and that on Diseases of the Optic Nerve. The chapter on Sympathetic Ophthalmia has been quite recently amplified by an article in the Royal London Ophthalmic Hospital Reports. Altogether the book is, for its size and pretensions, incomparably the best we know of both for the student and the practitioner.

THE IRISH GRADUATES' ASSOCIATION AND DR. MACNAUGHTON JONES.

THE following resolutions were passed at a late meeting of the above Association:—

1. The Council of the Irish Graduates' Association desire to convey to Professor Macnaughton Jones, of Cork, their sympathy with him under the trying circumstances in which he has been lately placed, and to express their opinion that he acted with the best of his judgment as a physician, and in accordance with the ordinary rules of professional propriety.
2. The Council also consider that the thanks of the profession as a body are due to Professor Jones for the able manner in which he defended the action of a medical attendant, responsible for the life of his patient, as no physician or surgeon should be held responsible for the result of treatment if due skill and care have been devoted to the case entrusted to him. They clearly recognise the incompetency of any non-medical authority to pass judgment on a purely medical question.
3. That a copy of this resolution be sent to the editors of the principal medical journals.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES.

Mr. R. L. Charrington, late of Carshalton, bequeathed £1000 each to the Earlswood Idiot Asylum and the Hospital for Incurables, Putney. Miss Ann E. Watts, late of Thornhill-crescent, Islington, bequeathed £1000 each to the Great Northern Hospital and the Royal Free Hospital, and £500 each to the London School of Medicine for Women and the East London Hospital for Children. The Misses Brooke have given £50 to the Adelaide Hospital, and a similar amount to Mercer's Hospital, Meath Hospital, and to the Building Fund of St. Mark's Ophthalmic Hospital, Dublin. The Bishop of Cork has given a donation of £50 to the Hospital for Incurables, Cork.

THE LANCET.

LONDON: SATURDAY, OCTOBER 30, 1880.

THE "nursing department" at Guy's Hospital has been again brought prominently before the public, and the "system" which the unhappy experience of the last few months has shown to be "in every respect mischievous," is apparently as mischievous as ever. On this occasion a nurse in the surgery ward attended to a "scalp wound," and sent the patient away from the hospital. The next day he returned, and on examination by a surgeon it became known that he had *also* a fracture of the skull. It is reassuring to be informed as a "deliberate opinion" that the lapse of time between his being sent away and his return the next afternoon did not in any way accelerate the death of this patient; but the fact remains that for a man who had been knocked down by a cart and sustained a fracture of the cranium to have his wounds dressed with a lotion and be sent away from a hospital, particularly when he was "not sober, but smelt of beer," was "not advisable." The nurse herself admits, looking back on the case, that the treatment adopted was not advisable, and we have it on the authority of a member of the staff that it was not. The nurse, however, did her best. She even seems to have taken considerable pains with the case. She made an examination round the wound as far as she could, and "came to the conclusion that none of the bones were broken!" Could any policeman have done more? The nurse of the surgery ward is clearly entitled to as much sympathy as we are accustomed to extend to the police when they blunder in their discrimination between the drunk and the dying. It may even strike the public that we are wont to be a little hard on the police for their blundering, seeing that a trained nurse specially retained on the "nursing department" of a large metropolitan hospital, and placed in charge of its "surgery ward," may fall into the same error.

The only fault in this case would seem to have been the effect of an omission to instruct the nurses that in cases of difficulty they might call in "further advice," and so distribute the responsibility; and that there would be nothing derogatory to the dignity of a representative of the "nursing department" in "consulting the surgeon." He would, in this instance, have coincided in the opinion that "none of the bones were broken," and then the surgeon's evidence would have been available to support the nurse's evidence, and no possible unpleasantness could have ensued. At the risk of offending the Governors of Guy's Hospital, we venture to suggest that some arrangement of this nature should be embodied in a formal rule. The nurse concerned in the present case said, "As to directions with regard to consulting the surgeons, I have had none directly." We cannot think the Treasurer, or even the Matron, could seriously object to giving such directions. There is nothing in itself humiliating in "consulting" a surgeon, and considering that, after all, Guy's Hospital was intended to be a comfort to the poor, it might be well to make this small concession. It would probably be deemed a pity to do anything which might

seem to imply that the institution could not be carried on by the Governors independently of the staff, but a mere formal consultation with one of the surgeons, or even a physician, in a case of obscurity should be gracefully tolerated. The only persons who could be reasonably expected to object to such an arrangement would be the medical officers. There used to be a feeling prevalent in the minds of medical men attached to hospitals that unless a patient applying for relief were at once seen by themselves, or one of their professional representatives, they would rather not have anything to do with the case. At some of the institutions within our knowledge—neither small nor unsuccessful in their way—the regulations were so definitive and exacting that if a nurse had presumed to uncover a wound or apply a piece of lint or sticking plaster, her zeal without knowledge would have been recognised and rewarded with instant dismissal. That was under the old system, when the dressers of a hospital acquired a practical knowledge of their art by themselves doing the whole of the dressing, and when every casualty was attended by an experienced student, in all cases of the least gravity under the personal superintendence of a qualified house-surgeon! In those days "nursing" was not a *department*, and nurses did not speak of "consulting" a surgeon, but simply acted as servants doing a master's bidding.

What will the Medical Faculty do under the circumstances? They have been told in no ambiguous terms that they *must* accept the system which makes the lay government supreme in all hospital arrangements. This is part of that system. Probably some new "directions" may be issued for the guidance of nurses, and in future these persons will "consult" the surgeon; but is the profession, and is the community, are the sick poor, to understand that the physicians and surgeons attached to Guy's Hospital agree to administer the charity on such terms? Is this a satisfactory discharge of public duty? Let personal interests and recondite considerations as to the school and the hospital be set aside, and the simple question receive a plain answer—can any staff, humiliated and subordinated as this medical staff has been humiliated and *is* subordinated, discharge its duty to the sick poor with credit to itself and the profession to which it belongs, or with a sincere feeling of self-respect, not to speak of dignity? We think not, and the profession thinks not. Already the staff at Guy's Hospital has "withdrawn" and "conceded" until the position it occupies is logically untenable and altogether incomprehensible. It is time the patient's standpoint was taken in this unhappy controversy. No medical man can be justified in lending his name and the authority of his status as a practitioner to a system of treatment by nurses, under the control of a treasurer, and matron, and governors who are all lay persons, doing, or affecting to do, medical work. The staff of a hospital cannot take the place of help-meets to the lay authorities. The institution is a medical charity, and all that relates to the treatment of patients must be directly under medical control. The existence of a "nursing department,"—which it seems is also a surgical department,—is fatal to the medical discipline of a hospital. The staff should pluck up courage to tell the Governors that they "must" accept the system public prudence and the interests of the sick poor require. If the Governors of Guy's Hospital are not prepared to accept the position to which common-

sense and public safety point, let the medical staff retire, and leave the future of this deplorably discredited hospital to unfold itself.

The announcement that at a meeting of the medical and surgical staff, and the lecturers, held last week, a resolution was passed earnestly begging Dr. HABERSHON and Mr. COOPER FORSTER "not to carry out their intention of resigning their appointments," will not fail to stir the profession with a feeling anything but sympathetic. There is no sufficient excuse or apology for the course pursued. The possible closing of the hospital and school might cause some private loss and a trifling public inconvenience, but what are such contingencies as these to the crying evil of a surrender of principle, and the creation of a grave scandal? It is time to tell the medical staff of Guy's Hospital that its policy is out of harmony with the conscience of the great body of practitioners to which it belongs. If the physicians and surgeons of this important institution are animated with a desire to uphold the honour of their profession, they must clear their position and revise their policy. We have no wish to ignore the efforts they have made, or to undervalue any successes they may have gained. It is much to have prevented the introduction of a sacerdotal system and sisterhood; but more remains to be done, and, rather than accept a position which must needs cripple them, they should resign.

THE operative measure brought before the notice of the Clinical Society at its last meeting by Mr. HENRY MORRIS is sure to attract attention and to receive criticism. It is one more instance added to the increasing list of cases where the propriety of surgical interference in the treatment of disease affecting an internal organ is to be duly considered. The time has gone by when such interference was regarded with mistrust and met with unflinching opposition; for it would seem that the fear nowadays is lest surgery should be too venturesome and should attempt too much. The justifiability of excising a calculus from the kidney in the earlier stages of its formation has, indeed, been often questioned, only to be sternly discountenanced. It was held to be a rash, absurd, and even a dangerous procedure by Sir BENJAMIN BRODIE and many writers on calculous disease, both before and since his time. And it must be confessed that there were grounds for this condemnation, not, however, those which made the measure a dangerous one in itself, for these have been shown to be of slight account; but those which argued from the facts of the known history of renal calculus—its frequent encystation or passage down the ureter into the bladder. "Nephrotomy," as distinguished from "nephro-lithotomy" (which Mr. MORRIS has termed the operation of excision of a stone from an undistended kidney) falls under quite a distinct category. For nephrotomy is applied to the incision of an organ already so diseased as to be past functional recovery. Nephrotomy has been long practised; nephro-lithotomy is quite a novel procedure. The objects of the operation are at least twofold—the one immediate, the other indirect. By nephro-lithotomy the surgeon seeks to relieve the patient from the more or less prolonged suffering entailed by the presence of so irritating a body as a concretion in the kidney. He also desires by the removal of this source of irritation to forestall those structural changes which so frequently ensue if a calculus re-

main in the organ. It is almost inconceivable that a stone should be lodged in the kidney without setting up such changes. They may be comparatively trifling; the stone becomes encysted in a calyx, and the secreting substance around it becomes atrophied and indurated. But at any time this calculus may be dislodged, and, if it be not small enough to traverse the ureter, may be arrested there or in the pelvis, and thus become the source of hydronephritic disorganisation; or by its presence it may excite pyelitis, with its long train of destructive disease. In either case the organ is rendered a useless encumbrance, if it be not an actual source of danger to life. Even where the stone traverses the ureter it enters the bladder, and after its passage from the kidney it may have to be removed by lithotritry or lithotomy from that viscus. It is obvious that much suffering and danger to life would be obviated were it possible always to remove the primary calculus or calculi from the kidney itself. This is what nephro-lithotomy is intended to do. Before, however, it can be regarded as an essential operation, it must be shown that other measures for relief are inadequate.

These measures are those which medicine affords, and it must be confessed that attempts at the solution of calculi by the long-continued administration of alkaline remedies are not so efficacious as might be inferred from their known action upon the urine. Many a case submitted to a most prolonged treatment has been apparently uninfluenced by it, and in the case of oxalic calculi no "solvent" administered by the mouth has ever had the least effect. Without wishing to take too pessimist a view of the medicinal treatment of calculus, it must still be admitted that the improvement is very slow, and the actual solution of the calculus probably very slight under any method of treatment. The part assigned to medicine lies really more in the prophylaxis of calculus than in its cure.

If, then, it came to be clearly recognised that a renal calculus, when formed, tends to increase, or at any rate to remain uninfluenced by remedies, that its very presence is a source of grave destructive disease of the kidney, as well as a continual cause of suffering, it will be more and more admitted that an operation for the removal of the calculus at the seat of its formation, instead of being absurd and rash, is rational and wise. Whether opportunities for such an operation will be frequent is doubtful, but it is probable that those cases where the early symptoms are most marked are just those where the calculus is most readily removed. The operation itself, except in the case of large branching calculi, as related by Mr. BARKER, should not be considered dangerous; and even the persistence of a urinary fistula may be set off as a very minor trouble compared with the great relief afforded by the removal of the stone. We feel then assured that the operation is a justifiable one, and are of opinion that it will become established in surgery; and it is not too much to hope it will, in course of time, almost supersede nephrotomy or nephrectomy, which are being had recourse to in more advanced stages of renal calculous disorder than "nephro-lithotomy."

THE approach of November terminates a most grateful lull in the strife of political parties, and calls Ministers to consider the complexion of their duty in regard to legislative

measures for the ensuing session. Superficial observers and keen partisans are apt to think that two or three great duties of the Ministry will swallow up all lesser ones. To promote the observance of the Berlin Treaty, and to preserve peace in Ireland, according to such critics, is work enough for any government. We do not think so disparagingly of the present Ministry. And amongst the minor pieces of legislation which we expect from them is a Bill for the Amendment of the Medical Acts. This kind of work is not sensational, and it does not appeal to the passions of partisans. But these are reasons rather for undertaking it than for declining it. The medical profession is expecting such legislation, and so are the medical schools and the licensing boards, in spite of a few indications of an attempt to believe that the change from a Conservative to a Liberal Ministry has brought some indefinable prospect of a new lease to old and thoroughly indefensible arrangements, and to a General Medical Council which has all the vices of an old body without the excuse of age.

We cannot bring ourselves to believe that the President and Vice-president of Council will be content with any slight excuses that may occur to them for neglecting a piece of reform that was in a fair way of being executed by a Conservative Ministry, and that contemplates improvement in both the process and the tests of medical education. It will be a heartless thing to allow successive generations of medical students to go on passing increasingly difficult examinations only to procure half diplomas. For ten years and more this system of half diplomas has been condemned by the Government and by public opinion, and by the opinion of the profession. The statesmen forming the existing Government, when last in power, framed a Bill in almost every way good, but defective in one respect. It contained no recognition of the gross faults of the Medical Council as a Council of Medical Education and Registration, and no provision for remedying them. But for this defect it must have passed triumphantly. A similar Bill brought forward now, with clauses amending the constitution of the Council, would be heartily supported by the profession, whose interests are not different from those of the public. Very plain facts have been adduced before a Select Committee showing the inefficiency and the costliness of the present Council, and that it is framed so as to do the greatest amount of talking and the least amount of work. All that the friends of reform ask the Ministry at present is to reappoint the Select Committee, granted by the last Government, which was dissolved with the Parliament, in the very middle of its work, and to give a fair hearing to those who wish to see medical schools and boards brought into harmony with existing opinion. It is known that some of the most eminent members of the profession were on the point of giving evidence before the dissolution. Is there anything in the dissolution to make their opinions less valuable, or the question of medical reform less urgent? Certainly not. We earnestly trust then that Ministers will include in their plans of work for the session of 1881 a Select Committee to be appointed early enough to report in time for legislation. There are no insuperable difficulties in the way. The profession is very unanimous in its demand for such a measure. Both parties in the State are committed to it. There can be no rest in the profession or in the

schools till it is passed. And the passing of it will lead to improved modes of teaching and examining medical students by which the public will be the gainers. There is opposition of course, but it is the kind of opposition that we expect and rather like. It is the opposition of interested and, in some instances, effete bodies. There could not be a greater libel upon the existing Ministry than to say that it waited for the support of such bodies before proposing measures of reform.

In a paper in the St. Thomas's Hospital Reports, 1880, Mr. WAGSTAFFE records the results of careful measurements of the femur and tibia in twenty-five cases of chronic disease of the knee-joint in young persons in whom the union of the epiphyses to the diaphyses may be presumed not to have occurred. The fact that lengthening of the femur may occur in such cases has been noted before, but this was an inquiry into its frequency or constancy, and whether it bears any distinct and definite relations to the position and kind of articular disease. In six of the patients only were the tibia and femur found unaltered in length, the sound limb being taken as the standard; but in two of these the disease commenced after the age of twenty, and they should, therefore, be excluded. In the nineteen cases in which alteration in length was found, the femur was lengthened in fourteen and shortened in one; the tibia was lengthened in four and shortened in six. In explanation of these facts, it is pointed out that the femur is much oftener the seat of disease than the tibia, and that the shortening of the tibia may be a part of the general malnutrition of the limb arising from interference with the circulation from enlarged glands in the groin. The manner in which disease of a bone may be supposed to increase its growth is by keeping up a chronic hyperæmia at the line of junction of the epiphysis and diaphysis, where the growth in length takes place; while a necrosis of the whole epiphysis, or extending to this line of ossifying cartilage, will cause shortening of the bone. Where the disease is purely synovial, or the articular surfaces are only quite superficially affected, there is not likely to be any effect produced on the length of the bone. In confirmation of these surmises it was found, on excising the joint in four of these patients, that in two, where no change in length of either bone was noted, the disease was purely synovial, or only affecting the bones superficially. In the two others, in each of which the femur was $2\frac{1}{2}$ cm. longer than its fellow, and the tibia normal, the disease "affected the femur with peculiar exclusiveness." In one of them there was noted acute congestion of the bone, not opposite to the tibial articular surface, but more deeply along the line of the epiphysis. The increase in the length of the femur was found to vary from .6 to 3.1 cm., and the average was nearly 2 cm. The practical deductions from these observations are, that by a careful measurement of the bones entering into a diseased joint the seat of that disease may be localised; if when long-standing no abnormality in length is found, it may be decided that the disease is synovial; if one bone is found lengthened it points to disease in it with hyperæmia along the epiphysial line, while shortening may be due to secondary general wasting of the limb, or to destructive disease of the bone reaching to the same line.

Annotations.

"Ne quid nimis."

THE SEAMEN'S HOSPITAL SOCIETY.

THE policy of the managers of the Seamen's Hospital Society is already beginning to bear fruit, and the withholding of a grant by the Common Council of the City of London shows that at length public criticism is being brought to bear on the conduct of the institution. It appears that the Seamen's Hospital Society holds an invested capital of £112,000, besides the use of the hospital premises rent-free from Government. The hospital is situated in Greenwich, on the side of the river opposite to the docks, and therefore inconveniently placed for the reception of sick sailors, who on their arrival in port have to be transported some way round or across the river before they are able to enjoy the rest and comfort which ought to be waiting for them close at hand. To maintain a hospital for sick sailors at a spot where no sick sailors land, is as absurd as it would be to place a casualty Hospital like St. Bartholomew's, for instance, on the top of Highgate-hill. The committee have partly seen this, and have so far condescended to stretch the assistance at their command, as to establish a dispensary where out-patients can obtain medicine without coming an afternoon's journey for it. But this dispensary does not touch the evil of having to transport sailors suffering from acute disease across the river. No wonder that increasing numbers of sailors seized with sudden and severe illness apply for admission at the hospitals on the side of the river on which the docks are situated. Moreover, it is difficult to see why the committee cling so fondly to their present building, seeing it is anything but fitted for a general hospital. Owing to the smallness of the wards, the expense of management and the difficulties of nursing must be in excess of what would be the case in wards of better construction, whilst there can be no doubt of their being less wholesome. The committee of the Seamen's Hospital love to pose as the friends of "poor Jack"; but really if they had his interests at heart they would provide him with a hospital better suited for his accommodation, and also place that accommodation near him, so that he might at once find refuge instead of having to seek for it in his hour of need. With a hospital building rent-free, accumulated funds of £112,000, and an obstinate adherence to a position which cannot be of the least value to the sick sailor, we do not think the Committee can make a very serious claim on private charity.

THE TREATMENT OF WHOOPING-COUGH IN GAS-WORKS.

A SERIES of recommendations on the treatment of whooping-cough in gas-works has been made to the Académie de Médecine. A commission was appointed some time ago consisting of three members, of whom M. H. Roger, the President of the Académie, is the sole survivor. He has presented a report to the Académie which is of some interest. Before considering the communication, he described the arrangement of the chambers for the purification of gas, and the chemical products which patients would breathe in them. The purifying chamber is a large room, with doors and windows freely open. Each contains twenty-four vessels, holding five cubic metres of depurating substance—lime and sulphate of iron, mixed with sawdust,—through which the gas has to pass. When the workmen are emptying and refilling one of these vessels the children with whooping-cough are placed around it, and inhale the vapours which escape. They are in an atmosphere containing ammonium sulphide, carbolic acid, and tarry products. The

statements made regarding the efficacy of this treatment are the following. M. Commenge records 169 cases in which the treatment was persevered with. In 20 the treatment failed completely, in 48 improvement was obtained, and 101 were cured. M. Bertholle merely states that, of 341 cases, 122 were improved and 219 were cured. Failures or deaths are not mentioned. M. Roger points out that these figures are too good to be quite satisfactory. A method of treatment which gives, of 510 cases, 490 ameliorations, and no death, would be indeed an admirable result. But besides the 490 cases improved there were, it appears, 671 cases not included because the treatment was not persevered in, and these probably include a large number of total failures. Moreover, the cases alleged to be cured were not carefully followed up. Evidently also slight and uncomplicated cases only can be treated in this manner. The remote situation of most gas-works, and the exposure involved in the treatment in winter, limit the application of this method. M. Roger thinks that it acts only upon one element of whooping-cough—the catarrh,—and that it is contra-indicated in febrile attacks of the disease, and would be positively dangerous in complicated cases. The method is, however, easy of use in some localities and in summer, and seems worthy of further trial in suitable cases, but it is desirable that its effects should be more exactly noted.

HOMŒOPATHIC PRACTITIONERS.

THE line of demarcation between homœopathic and regular practitioners continues sharply limited, in spite of the efforts of some homœopaths to break it down. Indeed, that it should be so is for the benefit of the follower of Hahnemann. He depends for his practice on the crotchets of his patients, who would not come to him were it not that they "believed (!) in homœopathy." This being so, the character of the practitioner is well known to his patients, and in suburban and country districts is well known also to the neighbouring medical practitioners. They can, and happily, as a rule, decline professional intercourse with one whose theories and practice are, as they believe, either foolish or dishonest, or both, and in any case fraught with peril to the sick. But medical men at a distance may know nothing of the character of any given practitioner, and, what is worse, they have no means of ascertaining. Homœopaths constantly endeavour, as every consultant can prove, to obtain consultations without declaring their mode of practice. Many a physician has been summoned by telegraph to a distance to find to his annoyance when he got to his destination that he was called to meet a homœopath. If he has his suspicions he may telegraph for information on this point, but if there is nothing to raise his doubts, he can scarcely do so, and has no means of learning the character of an unknown practitioner. Every qualified medical man's name appears in the Medical Directory. The list includes the names of probably hundreds of homœopathic practitioners, but in not a single instance is there any indication of the fact. The authorities of the Homœopathic Hospital lately sent, with characteristic audacity, to many medical men,—to all those connected with medical schools,—a circular descriptive of the arrangements of their hospital, and containing a list of the lectures, prizemen, &c. All of these are presumably practising homœopathy, but in not a single case is any intimation of the fact given in the Directory, nor, in the case of the physicians to the Homœopathic Hospital, is their appointment mentioned. We do not know whether this reticence is due to the fact that the Editor of the Directory declines to insert these appointments, or whether it is an indication that homœopathic practitioners are ashamed of their sect. Every medical man is assumed to be an orthodox (or, as we would prefer to say, a rational) practitioner, unless he is known to be a homœo-

path, and therefore those homœopaths whose names appear in the Directory without any indication that they are such are sailing under false colours.

"DENTAL SURGEONS," "SURGEON-DENTISTS," ETC.

It is interesting to notice the many proofs of ignorance or carelessness on the part of the public in reference to the working of the "Dentists Act." So far from that statute having any protective value for the community, it is, as we predicted it would and asserted it must be, a delusion and a snare. At present the Dentists' Register is a list of all the persons, with or without knowledge and qualification, who were, or claimed to be, in the habit of tooth drawing or making at the passing of the Act. Hereafter, that is to say, when the present race of "Dental Surgeons" shall have died out, the Register will comprise the names of those imperfectly educated and half-qualified persons who are simply licentiates in dentistry and nothing more, together with such fully qualified *surgeons* as may elect to have their names classed with the professors of a "specialty," which, in so far as it is *surgical*, cannot in the very nature of things have any *really* independent existence. We venture to think the number of medical men so minded will be exceedingly small. Meanwhile the drawers of teeth and hewers of jaw-bones luxuriate in the possession of a Register on which we regret to find the names of a few surgeons. They also call themselves "Surgeon-Dentists" and "Dental Surgeons" at pleasure, although there has been nothing surgical in their education, and they have no conceivable right to the title they claim. It is amusing to find members of the profession who short-sightedly or perversely agreed to accept the absurd phraseology of Sir John Lubbock's Bill, and, forsooth, thought it could "do no harm," now complaining of the results. They are simply the inevitable consequences of a serious misconception of the facts and a false policy. It would be ridiculous to pretend that we commiserate the surgeons, or greatly blame the "dentists" who have taken advantage of their weakness. At the same time we do pity the public who are victimised. The sooner qualified men take their names off the Dentists' Register and open up some new mode of marking themselves off from the mass of specialists, the better will it be for the country at large and a branch of the medical profession which has been practically stultified.

EXPERIMENTS ON SNAKE-BITE.

DR. ARTHUR STRADLING, of H.M.S. *Elbe*, writes to us to correct some errors in our account of his experiments with a rattlesnake, detailed in a recent number. His observations were not made with a view to the discovery of an antidote, but of a prophylactic, and were designed to discover a plan which shall render the body proof against the deadly effects of snake-bite. He writes: "The process, as I have it now, is so cumbrous and so perilous that in its present form it could never be of any practical use, and unless simplified would remain merely a matter of scientific interest. That it is capable of being simplified I feel certain. I am positive that I do much that is unnecessary, but it is difficult and hazardous to eliminate the useless from the useful, and it was through being in a hurry to arrive at a conclusion that I risked a certain omission in my affair with the rattlesnake. Three weeks afterwards I was bitten by a much larger one, nearly eight feet long, with at least a month's accumulation of fluid in his glands, and as active as a tropical day could make him; and this was attended with only local disturbance, by no means severe—nothing constitutional. Yes, my misadventure, nearly fatal as it was, has taught me much that was useful, much that will shorten my work, for I am determined to carry it out as far as I can myself.

Nothing that I do is wasted now. The grand *fact* is proved; the rest is a matter of detail—grave enough, no doubt, but only detail. I have no fear now that it may be said I threw my life away in pursuit of a visionary conceit. If I fail, someone else will succeed by avoiding the rock on which I come to grief. I commit everything, the smallest item, to paper before receiving a bite, and continue to note what I observe as long as I can hold the pen. That it will rank as a great discovery some day, I know, though I may not live to hear it hailed as such. So far I have completed the process with five distinct species of poisonous serpents, but whether each of the two hundred or so remaining species would require a separate course, or whether (as I believe) the venoms of many are identical, is uncertain. The difficulty of getting specimens renders my progress slow. All my experiments are made on myself; no animal will survive the preparation in its present form. If any man, in the medical profession or out of it, from a love of science, from a purely mercenary point of view, or for any other reason, or without any, will honestly join me and honestly share the labour and the risk, I will honestly share with him whatever *kudos* may attach to it eventually."

Dr. Stradling's work is evidently at present beyond the range of criticism. We trust, however, that he will take more care of himself in the future than in the past. If he falls a victim to what most would call rashness, but which is certainly remarkable self-devotion, we doubt whether any successor will be found to carry on experiments under such conditions.

FEMALE DRUNKENNESS.

THERE is a serious concurrence of opinion about the amount of female drinking that is going on in all classes of society. "Society" journals tell us that ladies only get through the monstrous duties of the London season by the help of stimulants assisted by chloral, and the daily newspapers give painful accounts of the drunkenness of poor women. Our contemporary the *Newcastle Chronicle* paints an appalling picture of this state of things in that town. It says: "If the police returns may be taken as a criterion, female drunkenness is fearfully on the increase in Newcastle. Scarcely a day passes but the Bench have a number of feminine inebriates to pass judgment on, and the number of confirmed cases that often come under their consideration is truly lamentable. . . . Amongst the many on Monday week was a young woman only twenty-one years of age, who actually made her fiftieth appearance, and another aged forty who for the forty-ninth time came up to answer the charge." Similar was the burden of the evidence before the Lords' Committee. We need not appeal to professional experience: it is only necessary to look about, and notice women of all classes, and of all ages, go in and out of the public-house unblushingly, not a few of whom, even in early life, present pictures of physical degeneration and ugliness which might well serve as a warning to their sex.

Whom shall we blame? Society, or the Legislature, or the Church, or ourselves as medical guides? There was a time when the profession might take a large share of blame. But that is not now. The profession, by its example and by its advice, is on the side of extreme temperance, and is constantly pointing out that alcohol can be taken only in its lighter forms by the run of people without harm of some kind. We shall not apportion the blame due to others. Our business is to record facts with the assurance, but without the details, of our own confirmatory evidence. Ladies should come to the rescue of their own sex. They have been slower than gentlemen in accepting the lighter forms of drink, and still evince an absurd preference for strongly fortified wines and for spirit. The Legislature should show itself ashamed of its past efforts. Of all useless and mocking

pieces of legislation in recent years the Habitual Drunkards Bill is the most so. We have good reason to know that it is absolutely a dead letter, and that not one Home, within the meaning of the Act, has yet been established. Mean-time, girls of twenty-one come up before helpless magistrates to be sent to prison for the fifty-first time.

DEATH OF DEPUTY SURGEON-GENERAL B. TYDD.

WE much regret to announce the death of Deputy Surgeon-General Benjamin Tydd, head of the statistical branch of the War Office, Whitehall-yard. Mr. Tydd was in his usual health on Friday last, and attended to his official duties at the War Office, returning to his country residence at Sevenoaks in the evening. On Saturday he was seized with symptoms of apoplexy, became rapidly unconscious, and expired on Sunday morning. Mr. Tydd entered the army as an assistant-surgeon on April 25th, 1851, and was shortly afterwards gazetted to the 23rd Royal Welsh Fusiliers, with which regiment he served throughout the Crimean campaign, being present at the action of Bulganac and the battle of the Alma (medal and clasp and Turkish medal). He was promoted surgeon in July, 1858, and remained with his regiment, the 23rd, for several years afterwards. In April, 1871, he became senior surgeon-major, and was transferred to the Royal Horse Artillery, proceeding to Bangalore in the Madras Presidency, in medical charge of the C Brigade, R.H.A. In March, 1879, he was promoted to the rank of deputy surgeon-general, and succeeded Sir Anthony Home, V.C., at the War Office on that officer's transfer to Cyprus. Mr. Tydd, who had been three times married, leaves a widow and several children to mourn his loss.

ARMY COFFEE TAVERNS.

WE are gratified to learn that steps are being taken to extend to the army the advantages of coffee taverns. Every one who has had anything to do practically with soldiers must be too well aware that drunkenness is the curse of the British army, and that very many men who have in them the making of splendid soldiers and excellent non-commissioned officers go to utter destruction from their inability to resist the fascination of drink. In our own time much has been done to improve the condition of the soldier, physically and morally, by providing him with the means of occupying his leisure time in a more rational manner than spending it in the public-house; but it is obvious that there is still wanting some counter attractions to the bright, cheerful-looking accommodation held out by it, and which can only be enjoyed on condition of contributing to its maintenance by the consumption of some of the stimulating drinks in which it deals. It is proposed now to establish coffee taverns, where all the advantages of warmth, light, and amusement may be enjoyed by the soldier outside the barrack gates without his being exposed to the temptation to indulge in intoxicating drinks, and to substitute tea, coffee, and other suitable refreshment in combination with recreation, books, &c., for the attractions of the gin palace and beershop. It is intended that these establishments shall be purely social, non-political, and unsectarian, and that they shall also be self-supporting. It is proposed to erect the first of them at Woolwich, and a committee has been appointed to take the necessary steps to do so. An appeal is made to military men especially, and to the general public, to contribute to so desirable an object by furnishing funds for the purchase of the necessary building. We cannot commend too highly so praiseworthy an attempt to raise the condition of the soldier, and to rescue him from those temptations which, alas! too often lead him into habits destructive alike of his physical and moral welfare, and from which, once contracted, he rarely, if ever, can emancipate himself.

THE INFLUENCE OF MUSIC ON THE CIRCULATION OF THE BLOOD.

DOGIEL observes that music excites both in men and in animals pleasant and unpleasant sensations, the effects varying with the individual and with the quality of the music. The Greeks long ago discriminated several forms of music according to their influence on the body, under the names of Phrygian, Lydian, Æolic, and Doric styles. Aristotle saw in music one of the most important means of education, and Plato considered it to be necessary that music should be studied from the thirteenth to the sixteenth year. Pythagoras held that music might be made serviceable in the treatment of various diseases. In short, the ancients were well aware that the human body is powerfully affected by music. Dogiel made a series of experiments both on men and animals, the results of which he sums up in the following propositions. (1) Music exhibits an influence on the circulation of the blood, both in animals and in man. (2) The blood-pressure sometimes rises, sometimes falls. These variations in the blood-pressure depend essentially on the influence of the excitation of the auditory nerve on the medulla oblongata, which is apparently in direct continuation with the auditory nerve. (3) The action of musical tones and pipes on animals and man expresses itself for the most part by increased frequency of the cardiac contractions, and hence it follows that the automatic centres of the heart act with greater energy. (4) The variations in the circulation consequent on musical sounds coincide with changes in the respiration, though they may also be observed quite independently of the respiration. (5) Strychnia increases the effect produced by stimulation of the auditory nerves on the circulation, whilst curara diminishes it. (6) Chloral hydrate, as well as ethyl alcohol and morphia (in a certain stage of the narcosis produced by them), diminish the action of the auditory excitation on the circulation. (7) The variations in the blood-pressure are dependent on the pitch and loudness of the sound, and on the tone colour. (8) In these variations of the blood-pressure the idiosyncrasies of the individual, whether man or animal, are plainly apparent, and even the nationality, in the case of man, has some effect.

THE ACCURACY OF THE MEDICAL REGISTER.

WE direct attention to an important advertisement in reference to the insertion in the Medical Register of changes of address or additional qualifications. There is perhaps a little red tape in the formalities necessary to be gone through, and these formalities have been the subject of some warm discussions between the General and the Branch Councils. After a six years' battle these discussions have ended in favour of the view of the Branch Councils. We are frequently receiving complaints of inaccuracies in the entries in the Register, some of them not to be easily explained. But by attention to the advertisement, registered practitioners will be able to blame the Council or its officers if there should be inaccuracies in their registration.

UNIVERSITY OF DUBLIN.

THE following resolutions were adopted by the Council at a meeting held on the 20th inst.: "1. That the Council are of opinion that in future instruction in surgery should be given by a course of lectures on the theory of surgery in the winter session, and a systematic course of demonstrations in operative surgery in the summer session. 2. That the secretary be directed to place on the College gate a notice that the Council will proceed at their next meeting, November 10th, to nominate to the Regius Professorship of Physic and to the Professorship of Surgery.

A YEAR'S WORK AT ST. BARTHOLOMEW'S HOSPITAL.

THE Medical and Surgical Registrars at St. Bartholomew's Hospital have just issued their annual report for 1879, from which it appears that the in-patients were 494 and 476 respectively on the first and last days of the year. The number of cases admitted during the year was 5820, making the total under treatment 6314; 5252 cases were discharged, including cured, relieved, and unrelieved. The deaths of patients were 586, exclusive of 37 cases brought in dead, and were equal to 10 per cent. of the completed cases. No less than 414 post-mortem examinations were made during the year. A table in the report shows the result of 467 cases of amputation within the hospital during the past ten years. In 110 of these cases, distinguished as primary and secondary operations, the mortality was equal to 20 per cent.; whereas in 357 cases of operation for disease the average rate of mortality did not quite equal 14 per cent. With regard to medical cases, the average duration of those that proved fatal during 1879 was twenty-one days, while the average stay in hospital of patients discharged was thirty-one days. The average stay in hospital of all surgical patients was nearly thirty-three days. The rate of mortality was equal to 17 per cent. among the medical cases; whereas the proportional mortality among the surgical patients did not exceed 5 per cent. It is to be regretted that, with the exception of the statistics of amputations, no table is given in this interesting report showing for comparative purposes a summary of the work in recent years. A retrospective table of admissions, recoveries, and deaths in recent years should invariably find place in all hospital reports, as it would materially add to the value of the statistics of the year to which the report relates.

CONGRESS OF ELECTRICIANS.

THE *Journal Officiel* publishes a report by the French Minister of Posts and Telegraphs, on the coming Congress of Electricians, and also a decree dated the 23rd of October, embodying the regulations, which are as follows:—

1. An International Congress of Electricians will be held at Paris under the presidency of the Minister, and will commence on the 15th of September, 1881.
2. Three vice-presidents will be chosen amongst the French, and three amongst the foreign members.
3. The Ministers of the Government of the French Republic, and all foreign Ministers who may take part in the Congress, will be *ex officio* members of the Congress.
4. The Palace of the Champs Elysées (Palais d'Industrie) will be placed at the disposal of the Commission authorised by the Government to organise at its own expense an International Exhibition of Electricity, to last from the 1st of August until the opening of the Congress.
5. The International Exhibition of Electricity will be placed under the patronage of the State.
6. The regulations of the exhibition will be submitted to the approbation of the Government, who will nominate the Commissary-General (M. Georges Herger).
7. The Minister of Posts and the Minister of Public Works are entrusted with the execution of this decree.

THE CELLS OF THE SPINAL GANGLIA.

THE structure of the cells of the spinal ganglia has been lately reinvestigated by Rawitz, who has employed a method advocated by Arnold. This consists in the immersion of the specimen in a 2 per cent. solution of acetic acid for four or five minutes, and then for from twelve to forty-eight hours in a 1 per cent. solution of acetic acid. They are afterwards teased out in glycerine, and finally treated with chloride of gold. The ganglion cells can be readily isolated, and appear to

be exclusively unipolar. The nerve-fibre from each courses first in a semicircle within the capsule before it leaves the cell. Apolar ganglion cells are frequent, but these are in no case separate, always lying within the same capsule as a unipolar cell. Besides the ordinary bean or club-shaped cells there are also small angular or cup-like structures, with short processes and large nuclei lying near the processes. Rawitz regards these as young cells. The supposed network on the surface of the ganglion cells he believes to be due to shrinking by the reagents. He was never able to see the spiral thread which Arnold has described as existing around the commencing nerve fibre, and regards it as an optical effect, due to folds in the outer sheath. The "polar nuclei"—i. e., an accumulation of minute nuclei near the place of exit of the fibre—he looks upon as belonging to the capsule, for they can, by proper treatment, be brought into view elsewhere in the capsule.

THE NEW ENTRIES.

THE information contained in the paragraph we published last week on this head requires to be supplemented by one or two additional particulars: Thus, St. Mary's Hospital School, the returns of which were then incomplete, has 25 fresh students in a total of 115. The Liverpool School counts 42 new entries (9 partial); whilst the figures given with respect to the University of Durham School need correction from 54 to 58 (29 being for part of the curriculum).

SYMMETRICAL NEURALGIA IN DIABETES.

DR. WORMS of Paris has called attention to the occurrence of symmetrical neuralgias in an advanced period of diabetes. He has recorded two examples—one affecting the sciatic nerve, and one the inferior dental,—and believes that the symmetry of the affection is a characteristic of this form, as also is its peculiar severity. It does not yield to the ordinary treatment of neuralgia—quinine, morphia, bromide,—and the pain varies in intensity with the amount of glycosuria.

THE death is announced of M. Peisse, whose name has been associated with medical literature for the last half century. M. Peisse studied medicine at Montpellier until 1826, when he settled in Paris. Although he still continued to follow the hospital clinics, the necessities of life prevented him from graduating, and compelled him to take up journalism. He was a constant contributor to the leading reviews, writing chiefly upon philosophical and medical subjects. In 1840 he translated into French a portion of Sir W. Hamilton, under the title of "Fragments de la Philosophie de W. Hamilton;" and a few years later published a French edition of Dugald Stewart's "Elements of the Philosophy of the Human Mind." His scattered articles on medicine were reprinted in 1857, under the name of "La Médecine et les Médecins." M. Peisse was an associate of the Academy of Medicine, and a member of the Académie des Sciences Morales et Politiques.

THE administration of carbolic acid in mistake for castor oil has received a fresh illustration in Glasgow Belvidere Hospital. The patient died in half an hour after taking the acid. In this case the bottles containing respectively the poison and the oil appear to have been similar in shape, colour, and size. After attention has been so repeatedly called to the obvious precaution of employing, for the storage of poisons, bottles of a shape and colour readily recognisable either in the presence or absence of light, it seems wonderful that accidents such as the above should still be of frequent occurrence. It is stated that in this case the grief of the nurse who administered the dose was so great as to induce serious illness.

ON the 23rd inst. the body of Mr. Francis Owen, M.R.C.S., of Leatherhead, was found in the Kennet and Avon Canal, between Hungerford and Kintbury. Evidence at the inquest showed that on the 21st, the deceased had left his home with the intention of going to Kintbury, but that, falling asleep in the railway carriage, he was carried on to Hungerford. It is supposed that in walking back along the bank of the canal to the former place (there being no vehicles at the station) Mr. Owen must have missed his footing and slipped into the water. The event has caused deep sorrow in Leatherhead, where the deceased, who was fifty years of age and the father of a numerous family, had been in practice many years.

DR. SPENCER, assistant librarian of the Royal College of Surgeons in Ireland, has resigned his appointment since August last, and has, we understand, been elected as medical officer to a dispensing district in the North of Ireland. The emoluments of the post are £100 per annum, and it is doubtful if the Council will elect another medical gentleman to fill the office, as from the small stipend attached they cannot expect any medical practitioner to retain it for any considerable period. The election will take place on November 18th.

THE Duke and Duchess of Connaught assisted, on the 23rd instant, at the ceremony of laying the foundation-stone of a portion of a new building situated at Mount Vernon, Hampstead, for the North London Hospital for Consumption. About a thousand persons were present, and a large number of purses were placed on the stone after it had been laid by his Royal Highness. In plan the hospital is a compact rectangular structure, about 163 feet long by 55 feet 6 inches deep. It is intended for 110 patients.

A NOTICE *in memoriam* of the decease of William Thomas Domville, C.B., M.D., R.N., Inspector-General of Hospitals and Fleets, which occurred some months ago, appearing in the obituary column of *The Times* of the 21st inst., several of our contemporaries fell into the error of regarding the announcement as referring to Dr. Henry Jones Domville, Inspector-General, R.N., who, we are happy to say, "is in a position" to correct the error.

THE Session of the Epidemiological Society of London will be opened on Wednesday evening, November 3rd, at 8 P.M., in the Council-room of University College, when the President, Sir Joseph Fayrer, will deliver an inaugural address, and Mr. Netten Radcliffe will read a paper "On Certain Appearances of Cholera since 1873 in the Countries lying between India and Europe."

A DISCUSSION on the Treatment of Typhoid at the instance of the Metropolitan Branch of the British Medical Association will take place at St. Thomas's Hospital on Nov. 10th at 8 P.M. Dr. Habershon will preside. The discussion will be opened by Dr. Bristowe; and Dr. Andrew Clark, Dr. Broadbent, Dr. Mahomed, Dr. Norman Kerr, and others will take part in it.

THE Belfast Graduates' Association have appointed the following medical gentlemen, among others, to co-operate with the Committee of Convocation and the London Graduates' Association in representing to the Prime Minister the views of the graduates of the Queen's University in Ireland—namely, Wm. A. McKeown, T. K. Wheeler, and Henry Whittaker.

THE School of Medicine of Edinburgh was opened on the 25th inst., in the Surgeons' Hall, with an address by Dr. F. W. Moinet.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Poplar.—The annual reports of the medical officers of health for this district, just issued, are for the year ending March, 1880. The practice of some officers of health, or sanitary authorities (we do not know which is to be blamed), of making their annual health-report for a twelve-monthly period not corresponding with that of the year, as ordinarily followed, is much to be deprecated.

Mr. Corner, the medical officer of health for the south district of Poplar, reports very favourably of the health of his district as measured by the rate of mortality during the year (18·8 per 1000 population). The fact of chief interest stated in his report, in connexion with the events of the year, refers to an outbreak of scarlet fever. Of this outbreak he says: "It was clearly shown that the disease travelled from child to child, house to house, and street to street, by the mingling of children from infected houses, first of the scholars attending the Glengall-road Board Schools, then of those at Christ-church and Pier-street Schools. Some instances were found of children attending school, or dispensary, or hospital, with infection still existing either in their persons or in those at home." Although the mode of dissemination of the disease was thus obvious, and both Mr. Corner and his colleague, Mr. Talbot, urged the utilisation of the authority's hospital for the isolation of cases, the authority refused to do so on the extraordinary ground that the number of cases was not deemed sufficient to justify them taking the step! In other words, the Poplar Board of Works, notwithstanding that they have a large infectious-disease hospital, recently erected at great cost, declined to make use of it for the purpose for which it was intended, and at the only time when such use could have been efficacious in arresting an infectious disease—namely, at the beginning of an outbreak. Doubtless the authority were under the impression that the hospital was much too expensive an agency to be put in action for a commonplace disease like scarlet fever. The outbreak of scarlet fever which, in the view of the authority, did not call for systematic measures of isolation on their part, gave rise to 117 cases and 34 deaths, in 68 houses, within the south district alone, before the close of 1879. Of these cases, three only were isolated by the Board of Works and six by the Board of Guardians.

The outbreak appears to have affected Cubitt Town particularly. Of this district Mr. Corner says that an examination of the houses "revealed a deplorably insanitary condition. Many had their kitchens flooded from time to time with rain, water, and sewage, rendering the basements damp and foul; others were damp from bad material and the absence of any means for preventing the rise of damp up the walls. Leaking roofs and spouts were common, as were defective traps and sinks, drains and closets, the indifference of tenants to these latter defects being general." In fact, Cubitt Town would appear to be much in the same condition as Canning Town, built under very similar local circumstances, in the neighbouring district of West Ham, across Bow Creek.

Of twelve cases of small-pox reported to the Authority nine were removed to their hospital. Probably not a single member of the Authority would entertain a doubt of the advantage gained for the community in the arrest of the contagion of the disease by this removal; yet a like advantage was refused in the case of scarlet fever! We must assume that the latter disease has not so much terror for the Authority as the former.

Mr. Corner has a remark, which deserves note, *à propos* of a painful case, on "the grave responsibility resting on medical men when called to cases of small-pox, in at once urging re-vaccination."

He gives also an instructive illustration of the value of the late Mr. Harry Leach's inquiry concerning the number of foul outfall sewers opening into the Thames notwithstanding the presumed interception by the Metropolitan Board of Works. In consequence of the result of this inquiry Mr. Corner inspected the whole of the riverside premises in his district, eighty-eight in number, and found in them no less than

forty-nine instances of privy outfalls into the stream. It is to be hoped that the other metropolitan medical officers of health of riverside districts have followed a like course in this matter to that adopted by Mr. Corner.

Mr. Talbot, the medical officer of health for the Poplar North District, reports on the whole as favourably of his district as Mr. Corner of the South District, but returns a higher rate of mortality (20·6 per 1000, as compared with 18·8). Mr. Talbot describes his district, which includes the greater part of Bromley and almost the whole of Bow, as, gauged by its death-rate, holding a position intermediate between a rural and a central metropolitan one. He attributes this favourable position to the operation of the Metropolitan Building Acts, in regulating the arrangement of buildings erected during the last few years. These Acts, he observes, "if erring, as some think, on the side of leniency as regards foundations, at any rate ensure thorough ventilation; and probably it is wiser to allow any miasm which might arise from the land a house is built upon to be dispersed by natural ventilation than to oblige the speculative builder to lay down a few inches of concrete; in fact, to build the house over a large trap, which would be tolerably sure, sooner or later, to prove defective and admit into the house at one place all the gases generated over the whole area; as a matter of fact, the houses put up of late as dwellings for artisans are not found to engender disease of any kind, nor is epidemic disease more fatal or more lasting in them than in houses built upon what is popularly supposed to be a more trustworthy foundation." This is the most noteworthy expression of opinion in the report. We give it without pretending to understand it. Mr. Talbot has somehow mixed up together questions of foundations and site; and comparative data of sickness and mortality derived from "houses put up of late" cannot be of much value. He is of opinion that to make the Sanitary Authority's infectious-disease hospital a success the admission must be free. We fully agree with him in this respect, and in the justness of his reasoning why such a course should be adopted by the Authority.

LONDON "DUSTING": ST. PANCRAS.

A report has been presented to the vestry of St. Pancras by the medical officer of health, Mr. Shirley F. Murphy, which ought to be in the hands not only of every vestryman of that district, but also of every vestryman in the metropolis. Great as is the continuous scandal of metropolitan "dusting" generally, in the course of the past and the present year, this scandal in the parish of St. Pancras assumed a magnitude previously almost unheard of. In the past summer, indeed, the operations of the Sanitary Committee of the vestry in procuring the removal of nuisances arising from the accumulations of the dry refuse of houses in dust-bins were brought to a standstill for some time from the negligence of the dust contractors, practically uncontrolled by the committee of the vestry, under whose regulation they presumably were. An indescribable state of nuisance from accumulated refuse grew up in the parish, and the ratepayers were helpless both against the contractors and an apathetic committee. The condition was not a new one, although latterly more accentuated, and from time to time the vestry have devoted a purposeless attention to it, allowing themselves to be easily foiled in any relief to the district by combinations of wharfingers and contractors, although the termini of the great lines of railway running to the north lie within the parish. Early in the present year, however, a special committee of the vestry, appointed to consider the question, called for a report from the medical officer of health on the subject, and this report is now before us. This report, after describing briefly the sanitary condition in which the parish is placed by the imperfection of the arrangements for "dusting," proceeds to point out the necessity for such arrangements being made as will admit of the frequent and systematic removal of the "dust" from houses (Parliamentary power being obtained to facilitate such arrangements, if necessary), and, finally, describes, from actual inspection of its action in other towns, a method in which the removal may be dealt with and in a measure utilised by the action of fire. These suggestions will add a greater gravity to the responsibility already existing upon the Vestry of St. Pancras, and other metropolitan Vestries, to deal effectually with the "dust" nuisance. Indeed, we are glad to learn as we write that Paddington has already been seeking information independently as to the disposal of

the "dust" of that parish in the way Mr. Shirley Murphy suggests. We could have wished that Mr. Murphy's report had contained some information on the feasibility of a daily removal of dust. He refers to the City and many Continental towns in illustration of such removal. But there are many places in Great Britain where a daily removal of dry refuse could have been studied with advantage in view of the adoption of such a practice in the metropolis. Let us hope that this report indicates an intention on the part of St. Pancras to deal with the subject seriously. We observe that the report was presented to the Special Committee for which it was prepared in May last; but if we ask what the Vestry has done since it must be confessed that there are too few empty dust-bins in the parish to echo a clear reply.

HOSPITAL PROVISION FOR INFECTIOUS DISEASES IN THE METROPOLIS.

There is little doubt that Sir E. H. Currie was right when, at the last meeting of the Metropolitan Asylums Board, he described the hospital provision for the isolation of infectious diseases on the north side of the Thames as inadequate (or, to use Dr. Forster's phrase, "altogether inadequate"); but there is equally little doubt that the Board was right in deciding that it was inexpedient to take measures to increase their hospital accommodation at the present time. The Board, indeed, would be singularly ill-advised to attempt to acquire additional sites for hospital purposes until the questions connected with the Hampstead Hospital are fully set at rest, and not improbably until the law relating to the acquisition of sites is amended. However ill-provided North-Eastern London may be with hospital accommodation for the isolation of infectious diseases at the present moment, having regard to the public-health point of view, it is seriously to be questioned whether it is incumbent upon the Metropolitan Asylums Board to take action to remedy the matter until the Legislature has taken measures to relieve it, and also sanitary authorities, from the very anomalous position in which they are now placed from the imperfect state of the law on the subject. It is to be trusted also that the public may have some better assurance of the capacity of the Board to deal with this question of hospital sites and increased hospital accommodation from a public-health point of view than it now possesses. We must take exception to Sir E. Currie's description of the removal of infected sick from various places on the south of the Thames all the way to Deptford Hospital, as a disgrace (on account of the distance over which some have to be carried) to a civilised community. It may be an unfortunate necessity, but having regard to the circumstances of the case and the provision of hospital accommodation for infectious diseases which has already been made in the metropolis as compared with other great civilised communities, to stigmatise this necessity as a disgrace is an abuse of language.

COMPULSORY VACCINATION.

At the recent North Wales Poor-law Conference, held at Bangor, a paper was read on "Compulsory Vaccination and its Results," by Mr. J. Oswald Bury, clerk to the Wrexham Union, from which we take the following instructive facts:—"Small-pox now rarely appeared in the Wrexham district, there having been only two deaths from it during the last nine years. In the sixteen years 1833 to 1853 the number of deaths in the union from small-pox was 315; but in the succeeding twenty-six years, after the passing of the Compulsory Vaccination Act, there were only 69 deaths from the disease. In the years 1838 and 1848 small-pox appeared to have raged in the district, and in several of the deaths registered he had found page after page, in many cases with six, and in others with eight, out of every ten deaths, registered as caused by this disease. In one parish, the largest and most populous in the union, the death-rate from small-pox averaged in 1838 20 per cent., and in 1848 25 per cent., of the total number of deaths from all causes. In the returns of children whose births were registered in the years 1876 and 1877 the North Wales unions figured remarkably well, only about 2 per cent. of the entire number of children born in those years being accounted for by the vaccination officers. As registrar and vaccination officer in the Wrexham Union, he had always found the Act cheerfully complied with and taken as a matter of course, so that the people felt no greater compulsion in having their children vaccinated than in having them registered. He had not had a single prosecution for

non-vaccination, a fact which was perhaps due in a great measure to fair reasoning with the parents, and an endeavour by the officers to make the Act popular."

In the discussion which followed the reading of this paper Captain Verney contended that the vaccine lymph should, as in Belgium, be supplied direct from the calf, and that greater care should be exercised in carrying out compulsory vaccination. Mr. J. Thomas (clerk to the Bangor Union) said that he never found any difficulty in carrying out the measure, nor to his knowledge had there been any prosecutions for offences against the Act. On the motion of Mr. B. T. Ellis, a resolution was carried in favour of the system of compulsory vaccination.

THE METROPOLITAN WATER-SUPPLY.

A meeting of delegates for the vestries and district boards of the metropolis met on the 20th inst. in the Vestry Hall, St. Martin's-in-the-Fields, where the following resolution was adopted: "That as the report of the [Parliamentary] Committee of Session II., 1880, on London Water-Supply, recommends that the Government should introduce a Bill to constitute a water authority of a representative character, in order that the supply of water in London should be under the control of some public body representing the interests of the consumers, a communication be addressed to the Home Secretary to learn if notice of such Bill will be given by him, and limited to such objects." A further resolution, to the following effect, was proposed but rejected as premature: "That the Home Office be invited to state whether it will undertake to present the requisite evidence, and whether it will arrange between this and the meeting of Parliament for a valuation of the works and plant of the companies, for a completion of the audit to the 31st December of the accounts of all companies, and for a report of the present condition of their works, and the outlay requisite for their transfer in perfect order."

THE METROPOLITAN MILK SUPPLY.

At a recent meeting of the St. Olave's District Board one of the members stated that the milkmen of London had an organised system of escaping the penalties that the law inflicted upon them. On the inspector warning a milkman that a repetition of offence in respect to adulteration would be dealt with by law, the business was transferred, no alteration being made in the quality of the milk.

At Scarborough a curious example of conflicting chemical evidence occurred in the police-court on the 15th inst. The Sanitary Authority took proceedings against certain inhabitants of the town in order to secure the closure of a well, the water of which was alleged to be impure and injurious to health. They supported their case by the evidence of the borough analyst, Professor Wanklin, and the medical officer of health, Dr. Taylor. For the defence Professors Redwood and Atfield were examined, both of whom admitted that the water was not of the purest, but expressed the opinion that the impurity would not render it unwholesome. In view of the differing opinions of the analysts, the magistrates dismissed the case.

An attempt would appear to have been made, at the instigation of the Local Government Board, and by the agency of its inspector, Major Tulloch, R.E., to induce the several sanitary authorities in the Barton Union (Lancashire) to combine for the purpose of erecting an infectious-disease hospital. It would seem, however, that several of the authorities have made arrangements with either the Monsall (Manchester) infectious-disease hospital or the Children's Hospital at Pendlebury for the reception of patients, and hold these arrangements to be sufficient. The Local Board of Barton, however, proposes to proceed with the erection of a hospital for their own district.

Dr. Wallace, in his report for Greenock for the month ending the 2nd October, notes eight cases of typhus. These cases occurred in five families, and were directly or indirectly associated with each other. Dr. Wallace thinks it quite possible that the first of the series may have caught the infection in Ireland where the patient had been visiting. It has been held desirable to dispose of the contents of the dry-earth closets of the infectious-disease hospital by burning, a case of small-pox occurring in the town having originated, it is believed, from communication with the person engaged in the duty of cleansing them.

Dr. Dixon, the medical officer of health for Bermondsey, appears to be regularly following the course of advising his Authority on the actual meaning of Dr. Frankland's phrase, as applied to Thames water supplied by the metropolitan water companies, "unfit for dietetic purposes." He ingeniously translates the chemical data on which it is founded into forms which may be apprehended by ordinary individuals, and shows that, however accurate the results of "chemical analysis" may be, they are imperfect until compared with the results of "medical analysis." He shows, in fact, that the phrase cannot be justified by chemical analysis alone.

The Bedford-park Estate, Acton, dear to the lovers of "Queen Anneism" in architectural art, has been the subject of an inquiry under directions from the Local Government Board. The proprietor of the estate wishes to dis sever it from Acton and attach it to Chiswick parish, for convenience of sewerage ostensibly, but, according to popular gossip, from a desire of the inhabitants (or some of them) to become associated with the more aristocratic neighbourhood. Mr. R. Morgan, C.E., held the inquiry; but Acton is loth to lose the Estate, while Chiswick does not appear to be anxious to annex it. The result of the inquiry has not yet been made known.

A curious discussion occurred at a vestry meeting at Westbury-on-Trym, near Bristol, on the 1st inst. It related to the use of a sum of money (£45), the unused balance of subscriptions made in aid of the sufferers from an outbreak of cholera in 1854. A proposition to devote this sum, with other surplus parochial funds, to the payment of the expenses of lighting the church, so as to make it available for evening service in the winter, was set aside, and it was decided to reserve it for use in cases of sickness among the poor.

At a recent meeting of the Middlesborough Rural Sanitary Authority a communication was read from the Enisborough Rural Sanitary Authority, asking the co-operation of the former in memorialising the Local Government Board respecting the more effective control of infectious diseases, by advocating a Bill in Parliament to make it compulsory upon medical men and heads of householders to notify to the Sanitary Authority all cases of infectious diseases coming under the observation of the former, and the control of the latter.

An abortive inquiry was recently opened at Gloucester, by Mr. Thornhill Harrison, C.E., under instructions from the Local Government Board, concerning an alleged pollution of the Severn by the Gloucester Corporation. The inquiry had been promoted by the chairman of the Severn Fishery Board, but when Mr. Harrison visited Gloucester for the purpose of the inquiry, the fishery board for some inscrutable reason refused to tender evidence in support of their case, and the inquiry in consequence had to be adjourned *sine die*.

The "disinfecter" of the St. Saviour's Board of Works is reported to be "always seen in the same suit of clothes." Hence a serious question for the Board. If, as is to be inferred, the suit in question is the one he uses when engaged in disinfecting articles of clothing, bedding and furniture, also infected houses, may it not imbibe infection, and the "disinfecter" himself become a means of disseminating disease? Such is a question at present perplexing the Board.

An outbreak of scarlet fever at Blackheath has led to the disclosure of a nuisance in a particular cow-shed which would indicate that systematic inspection of their district is not a feature that the Greenwich Board of Works can have credit for. "Several weeks' accumulation of manure in a putrid condition, and which gave off a most offensive stench" is spoken of as having had to be removed from the shed.

Dr. Ballard, under instructions from the Local Government Board, has been investigating an outbreak of enteric fever at Millbrook, in the St. Germans union. At an interview with the Rural Sanitary Authority he attributed the outbreak to defective ventilation of sewers, water pollution, and contaminated milk, the latter, in his opinion, being responsible for the disease in twelve out of forty-seven families affected.

Sewerage works have been recently opened at Birkdale, of which the construction was entered upon in 1875. The process of sewage treatment adopted is that of Mr. F. Hillé.

A disagreement between the workhouse infirmary medical officers of St. George's-in-the-East, and which appears to be locally designated as "the Civil War," has been referred to the Board of Guardians and the Local Government Board for inquiry.

The question of providing an infectious-disease hospital at Ashted is under consideration.

Dr. Ainley has been usefully lecturing in the Central Hall, Halifax, on "Practical Hygiene."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The rate of English urban mortality showed an increase last week, and exceeded the average rate for the season. In twenty of the largest English towns, estimated to contain in the middle of this year a population of seven and a half millions of persons, or nearly one-third of the entire population of England and Wales, 4895 births and 3249 deaths were registered last week. The births were 310 and the deaths 26 below the average weekly numbers during 1879. The deaths showed, however, an increase of 176 upon the comparatively low number returned in the previous week, and were equal to an annual rate of 22.6 per 1000 of the estimated population, against 21.7 and 21.4 in the two preceding weeks. The lowest death-rates in the twenty towns last week were 16.5 in Birmingham, 16.7 in Portsmouth, 19.3 in Bristol, 19.4 in Oldham, and 19.8 in Leeds. The rates in the other towns ranged upwards to 27.5 in Bradford, 30.2 in Liverpool, 32.1 in Hull, and 32.5 in Leicester. During the past three weeks of the current quarter the death-rate in these towns averaged 21.9 per 1000, against 20.3 in the corresponding periods of the four years 1876-9.

The deaths referred to the seven principal zymotic diseases, which had steadily declined from 1239 to 564 in the eight preceding weeks, further fell to 472 last week; of these, 159 resulted from diarrhoea, 147 from scarlet fever, and 59 from fever, principally enteric. The annual death-rate from these seven diseases averaged 3.3 per 1000 in the twenty towns, and ranged from 2.1 in Birmingham, Leeds, and Plymouth, to 6.7 and 7.6 in Salford and Leicester. The 147 deaths from scarlet fever exceeded the number returned in any previous week this year, and showed the largest proportional fatality in Sunderland, Liverpool, and Leicester; the disease was nearly three times as fatal in the provincial towns as in London. Measles was most fatal in Leicester. The highest death-rate from fever (principally enteric) occurred in Salford, Brighton, and Portsmouth. The general fatality of diarrhoea showed a further decline, but the death-rate from the disease, which did not exceed 0.9 per 1000 in London, averaged 1.4 in the nineteen provincial towns. Diphtheria caused 11 deaths in London, 2 in Bradford, and 3 in Liverpool. Seven more fatal cases of small-pox occurred in London, but not one in any of the nineteen other towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had declined from 116 to 85 in the four preceding weeks, further fell to 77 on Saturday last; 12 new cases were admitted to these hospitals during the week, against 14 and 16 in the two previous weeks.

The deaths referred to diseases of the respiratory organs in London, which had steadily increased from 124 to 273 in the six previous weeks, further rose to 323 last week, and exceeded the corrected weekly average by 38; 213 were attributed to bronchitis, and 77 to pneumonia. The annual death-rate from lung diseases was equal to 4.5 per 1000 in London, and 5.7 in Liverpool.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 19.6 per 1000, against 18.8, 19.6, and 22.4 in the three preceding weeks, and was 3.0 per 1000 below the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged last week from 16.1 and 17.1 in Edinburgh and Aberdeen, to 25.3 and 25.8 in Perth and Leith. The deaths referred to the seven principal zymotic diseases in the eight towns, which had been 116 and 135 in the two previous weeks, declined last week to 107; they included 47 which resulted from scarlet fever, 17 from fever, 14 from

diarrhoea, 13 from whooping-cough, 13 from diphtheria, 3 from measles, and not one from small-pox. The annual death-rate from these seven diseases averaged 4.3 per 1000 in the eight towns, and was 1.0 above the average rate from the same diseases in the twenty English towns. The zymotic death-rate in the eight Scotch towns ranged from 0.5 and 2.3 in Aberdeen and Dundee, to 5.3 in Paisley and 7.1 in Leith; the high death-rate in the last-mentioned town was due to the excessive fatality of scarlet fever. The deaths referred to scarlet fever in the eight towns, which had been 30 and 52 in the two preceding weeks, declined last week, to 47, and included 25 in Glasgow, 15 in Edinburgh, and 5 in Leith. The 17 fatal cases of fever (including typhus and enteric or typhoid) were 6 less than those returned in the previous week; 9 occurred in Glasgow and one in Edinburgh, showing in each of those towns a considerable decline from the exceptionally high numbers in the preceding week. The deaths referred to diarrhoea, which had declined from 69 to 20 in the five previous weeks, further fell to 14, of which 8 were recorded in Glasgow. Of the 13 fatal cases of diphtheria last week 8 were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs (bronchitis, pneumonia, and pleurisy) in the eight towns, which had been 66 and 98 in the two preceding weeks, further rose last week to 120; the annual death-rate from these diseases last week was equal to 4.8 per 1000 in the eight Scotch towns, against 4.1 in London.

HEALTH OF DUBLIN.

The excessive rate of mortality in Dublin showed a further slight decline last week. The annual death-rate in the city has slowly but continuously decreased during the past six weeks from 39.3 to 33.7 per 1000. During last quarter the death-rate averaged no less than 34.6, and in the past three weeks of the current quarter the average rate has been 33.0, against 20.5 in London, and 21.7 in Edinburgh. The 197 deaths in Dublin last week were 2 less than those returned in the previous week, and included 36, or 18 per cent., which were referred to the seven principal zymotic diseases, showing a further decline of 14 from recent weekly numbers; 16 resulted from scarlet fever, 7 from diarrhoea, 4 from measles, 4 from whooping-cough, 3 from fever, and 1 each from small-pox and diphtheria. The annual death-rate from these diseases was equal to 6.0 per 1000 in Dublin, whereas it did not exceed 2.7 in London, and was 4.8 in Edinburgh. The 15 fatal cases of scarlet fever showed a further increase upon the numbers in the two previous weeks, and exceeded the number in any week since the end of June. The fatality of diarrhoea showed a further considerable decline from recent weekly numbers, but exceeded the corrected average for the season. The deaths from fever and from whooping-cough showed a marked decline; and those from small-pox, which had been 1 and 4 in the two previous weeks, declined again to 1 last week. The number of deaths under one year of age corresponded with the number in the previous week, and was equivalent to a very excessive rate of infant mortality.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

BEDROOM VENTILATION.

Mr. Lawson Tait has invented, and is now advocating, a very ingenious mode of ventilating and warming bedrooms. He uses what may be roughly described as a Tobin's tube, with an arrangement for filtering the incoming air and warming it by means of a lighted gas jet. The invention may be readily adapted to the purpose for which it is designed, and may even be given a much wider application to the warming and ventilating of rooms; but when he sees in his "little contrivance," as he judiciously terms his invention, an important step towards (if not the beginning) of a change which he is sanguine enough to hope will before long banish the deeply-cherished coal-fire from every house in the towns and villages of England, and banish also that (to him) barbarous element of room ventilation in England the fire-grate and chimney, we cannot follow his aspirations, notwithstanding even that they may be approved by "those who are accustomed to deal with questions of hygiene." Taking the cost of the "little contrivance" at the minimum suggested by Mr. Tait, 8s. to wit, add the cost of the gas and the gas-fittings where gas may chance to exist,

and calculate the number of houses where this addition to the cost of living would be an impossibility, the suggestion falls infinitely short of practicability. Persons accustomed to deal with questions of hygiene should have in view the requirements of the poorest people, and hitherto no means of securing the ventilation of bed-chambers have been devised or proved more effectual than the construction of a fireplace and chimney. Whatever tends to diminish the confidence of people in this matter, and to prejudice them against these means, merely helps to put money into the pockets of the cottage builder by encouraging him to build wherever he can avoid it without fireplace and flue.

DIPHTHERIA IN RUSSIA.

The Podolian branch of the Russian Red-cross Society reports that since the 15th (27th) August they have had nine sanitary detachments at work aiding the communities among which diphtheria prevails. These detachments include nine medical men, thirteen sisters of charity, and fifty-one assistants. Within the period they have been actively engaged there have been reported 4620 cases of diphtheria, of whom 1339 had died. In view of this formidable prevalence of the disease the Society had determined, from Sept. 12th, to strengthen their sanitary detachments, to invite the assistance of the most influential officials, and to request the Association of Ladies to collect linen and clothes in substitution for infected articles destroyed. It is proposed, however, to constitute a special commission to study the progress of the epidemic.

CHOLERA AT ALLAHABAD.

A correspondent of the *Pioneer* directs attention to the marked localisation of the cholera which prevailed among the troops stationed at Allahabad and in the Central Prison there early in the present year. The localisation was of a sort that has frequently been found in England to be dependent upon an infection of the water-supply or of some article, and he argues that if search had been made, after the English fashion, it is in the highest degree probable that causes of a like sort would have been found in operation in the Allahabad cantonments and prison. Of course it is assumed here that cholera has an element of infection in India such as it is held to have in England, whereas the infection attaching to cholera in India is a mere official contingency.

The Glasgow Dairymen's Association has taken exception to the conclusion of Drs. Russell and Christie on the cause of the late localised outbreak of enteric fever in Glasgow and the suburbs. It has endeavoured to traverse that conclusion by advancing data which appear to be inconsistent with it; but, as might have been anticipated, their data and arguments simply serve the purpose of giving greater confidence to the accuracy of the conclusion of the two reporters.

A correspondent calls our attention to the insanitary state of the Sunning-hill Schools, and the want of sufficient cubic air space for the children.

BRITISH MEDICAL TEMPERANCE ASSOCIATION AT BRISTOL.

A CONFERENCE of medical men was held at Bristol under the auspices of the British Medical Temperance Association on the 13th inst., to consider the following question:—"Has not the time arrived for the medical profession to give the public a scientific opinion with regard to the value of alcoholic drinks as beverages." The chair was taken by Dr. Brittain, and the debate opened by Dr. Ridge, the Secretary of the Association, in an affirmative answer to the above question. He stated that in Great Britain alone drink was the cause of 40,000 deaths annually; that it was responsible for nine-tenths of the crimes committed; was directly the cause of from 14 to 15 per cent. of the lunacy existing, and of three-fourths of the pauperism. The public would listen to a definite expression of opinion on the part of the profession; but the articles in the *Contemporary Review* only produced an effect of painful amusement at the diversity of opinion expressed by the writers. After considering the action of alcohol in health and disease, he
